

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

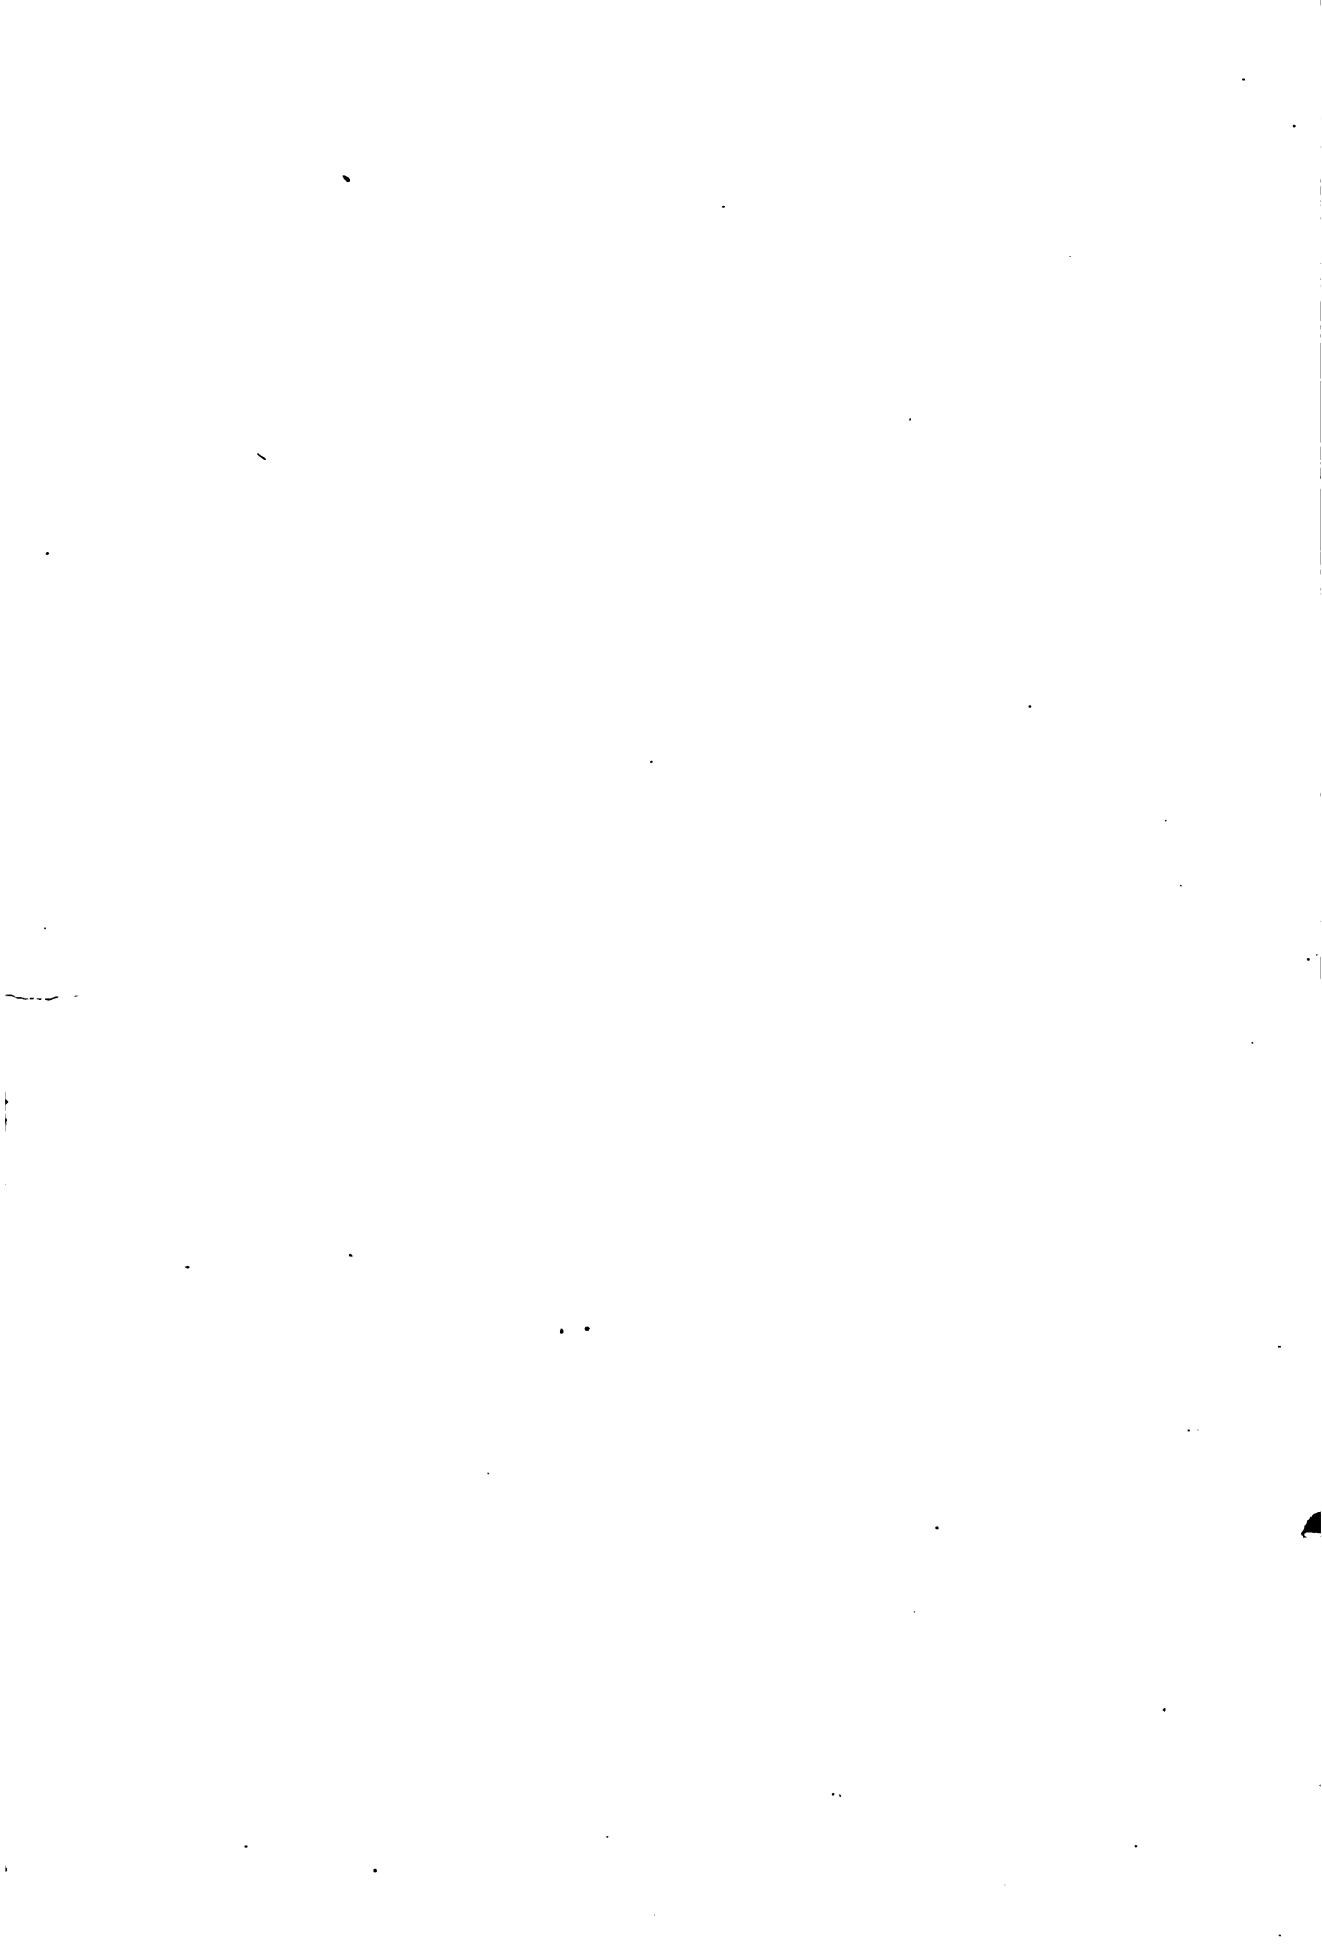

### About Google Book Search

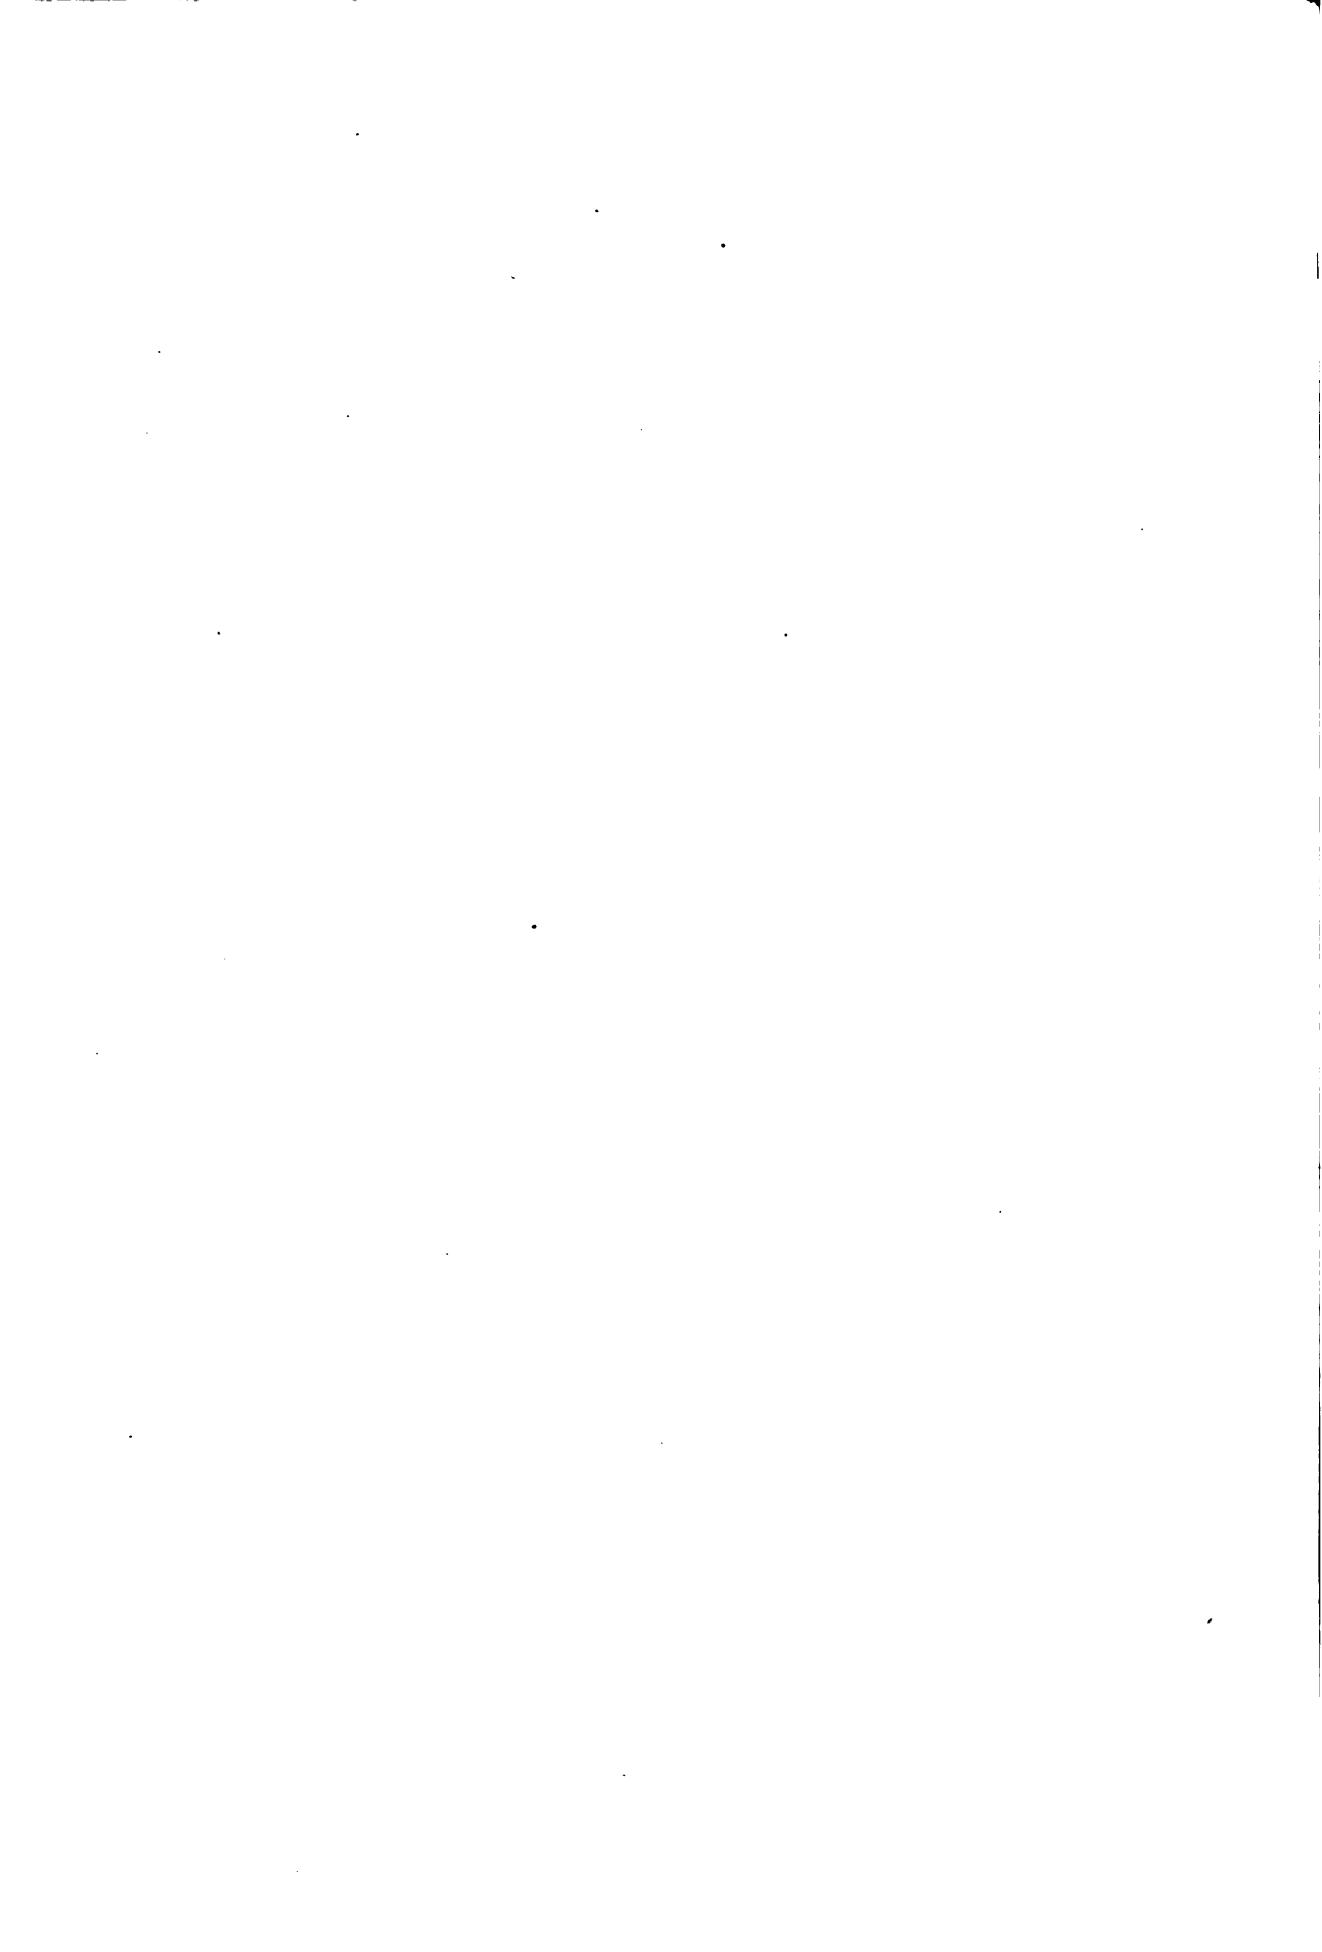

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

# AMERICAN EPHEMERIS

AND

## NAUTICAL ALMANAC

FOR THE YEAR

1 8 9 4

*FIRST EDITION*

---

*PUBLISHED IN COMPLIANCE WITH A JOINT RESOLUTION OF THE FORTY-SIXTH CONGRESS*

---

WASHINGTON:  
BUREAU OF EQUIPMENT.  
1891.

*JOINT RESOLUTION*

*FOR PRINTING THE AMERICAN EPHEMERIS AND NAUTICAL ALMANAC.*

*Resolved by the Senate and House of Representatives of the United States of America in Congress assembled, That there shall be printed annually at the Government Printing Office fifteen hundred copies of the American Ephemeris and Nautical Almanac and of the papers supplementary thereto, of which one hundred shall be for the use of the Senate, four hundred for the House of Representatives, and one thousand for the public service, to be distributed by the Navy Department.*

*Sec. 2. That additional copies of the Ephemeris and of the Nautical Almanac extracted therefrom may be ordered by the Secretary of the Navy for sale: Provided, That all moneys received from such sale shall be deposited in the Treasury to the credit of the appropriation for public printing.*

*Approved, February 11, 1880*

## P R E F A C E.

---

THE arrangement of *The American Ephemeris* adopted in the volume for the year 1882, and explained in the Appendix to that volume, has been continued without radical change to the present time.

The additions then made comprise more complete data for eclipses of the sun, diagrams showing the configurations of the satellites of Jupiter, data respecting the disks of Mercury and Venus for the reduction of meridian and photometric observations, and diagrams, with tables, for identifying any known satellites of other planets. The work is divided into three parts, as follows:—

Part I, *Ephemeris for the Meridian of Greenwich*, gives the geocentric and heliocentric positions of the major planets, the Ephemeris of the Sun, and other fundamental astronomical data for equi-distant intervals of Greenwich mean time.

Part II, *Ephemeris for the Meridian of Washington*, gives the ephemerides of the fixed stars, sun, moon, and major planets for transit over the meridian of Washington. The mean places of the fixed stars and the data for their reduction are also included in this part. The list of mean and apparent places of fixed stars has been greatly enlarged, for the convenience of field-astronomers.

Part III, *Phenomena*, contains predictions of phenomena to be observed, with data for their computation. Washington mean time is used in this part except in a few cases, notably that of eclipses, where Greenwich mean time was judged more convenient.

SIMON NEWCOMB,  
*Professor U. S. Navy, Superintendent.*

WASHINGTON, May, 1891.

## CHRONOLOGICAL ERAS AND CYCLES.

---

### *CHRONOLOGICAL ERAS.*

THE YEAR 1894, WHICH COMPRISES THE LATTER PART OF THE 118TH AND THE BEGINNING  
OF THE 119TH YEAR OF THE INDEPENDENCE OF THE UNITED STATES OF AMERICA,  
CORRESPONDS TO—

The year 6607 of the Julian Period;

- “ 7402-7403 of the Byzantine era, the year 7403 commencing on September 1st;
- “ 5654-5655 of the Jewish era, the year 5655 commencing on October 1st, or, more exactly,  
at sunset on September 30th;
- “ 2647 since the foundation of Rome, according to VARRO;
- “ 2641 since the beginning of the era of NABONASSAR, which has been assigned to  
Wednesday, the 26th of February of the 3967th year of the Julian Period;  
corresponding, in the notation of chronologists, to the 747th; and, in the notation  
of astronomers, to the 746th year before the birth of CHRIST;
- “ 2670 of the Olympiads, or the second year of the 668th Olympiad commencing in July,  
1894, if we fix the era of the Olympiads at 775 $\frac{1}{4}$  years before CHRIST, or near  
the beginning of July of the year 3938 of the Julian Period;
- “ 2206 of the Grecian era, or the era of the Seleucidæ;
- “ 1610 of the era of Diocletian;
- “ 2554 of the Japanese era and to the 27th year of the period entitled “Meiji.”

The year 1312 of the Mohammedan era, or the era of the Hegira, begins on the 5th day of  
July, 1894.

The first day of January of the year 1894 is the 2,412,830th day since the commencement of the  
Julian Period.

NOTE.—The mean time of semidiameter passing may be found by subtracting 0.19 from the sidereal time.  
 The sign + prefixed to the hourly change of declination indicates that north declinations are increasing;  
 the sign — indicates that north declinations are decreasing.

NOTE.—The mean time of semidiometer passing may be found by subtracting 0.19 from the sidereal time.

The sign — prefixed to the hourly change of declination indicates that north declinations are decreasing.

Note.—The semidiameter for mean noon may be assumed the same as that for apparent noon.  
 The sign — prefixed to the hourly change of declination indicates that south declinations are increasing; the sign + indicates that south declinations are decreasing.

Diff. for 1 Hour,  
 +9°.8565.

**FORMULÆ FOR THE REDUCTION OF THE POSITIONS OF THE FIXED STARS, USING THE NOTATION OF BESSEL, AND THE CONSTANTS OF PETERS AND STRUVE.**

**NOTATION.**

$\tau$ , the time, reckoned in units of one year, from the beginning of the Besselian fictitious year, (1893, December 30<sup>d</sup>.649 = 1894, January 0<sup>d</sup>.0—0<sup>d</sup>.351, Washington mean time),  
 $\alpha_0, \delta_0$ , the star's mean right ascension and declination at the beginning of the fictitious year,  
 $\alpha, \delta$ , the star's apparent right ascension and declination at the time  $\tau$ ,  
 $\mu, \mu'$ , the annual proper motion in right ascension and declination,  
 $\odot$ , the sun's true longitude,  
 $\Omega$ , the longitude of the moon's ascending node,  
 $\omega$ , the obliquity of the ecliptic,  
 $\Gamma$ , the longitude of the sun's perigee,  
 $\Gamma'$ , the longitude of the moon's perigee,  
 $\zeta$ , the moon's mean longitude.

**BESSELIAN STAR-NUMBERS.**

$$\begin{aligned}
A &= \tau - 0.34249 \sin \Omega && - 0.00011 \sin (3 \odot - \Gamma) \\
&+ 0.00410 \sin 2 \Omega && - 0.00005 \sin 2 (\odot - \Omega) \\
&- 0.02521 \sin 2 \odot && + 0.00010 \sin 2 (\odot - \Gamma') \\
&+ 0.00293 \sin (\odot + 282^\circ 4') && + 0.00009 \sin (2 \Gamma' - \Omega) \\
&+ 0.00025 \sin (2 \odot - \Omega) && + 0.00005 \cos \Gamma' \\
&- 0.00405 \sin 2 \zeta && + 0.00004 \sin 2 \Gamma' \\
&+ 0.00135 \sin (\zeta - \Gamma') &&
\end{aligned}$$
  

$$\begin{aligned}
B &= - 9.2239 \cos \Omega && - 0.0027 \cos (3 \odot - \Gamma) \\
&+ 0.0895 \cos 2 \Omega && + 0.0067 \cos (2 \odot - \Omega) \\
&- 0.5506 \cos 2 \odot && + 0.0024 \cos (2 \Gamma' - \Omega) \\
&- 0.0092 \cos (\odot + 281^\circ 3') && - 0.0023 \sin \Gamma' \\
&- 0.0866 \cos 2 \zeta && + 0.0008 \cos 2 \Gamma' \\
C &= - 20.4451 \cos \omega \cos \odot && \\
D &= - 20.4451 \sin \odot && \\
E &= - 0.0461 \sin \Omega + 0''.0014 \sin 2 \Omega - 0''.0033 \sin 2 \odot &&
\end{aligned}$$

**BESSEL'S Star-Constants.**

$$\begin{aligned}
a &= 3^\circ 07261 + 1^\circ 33684 \sin \alpha_0 \tan \delta_0 = \text{precession in right ascension} \\
b &= \tfrac{1}{15} \cos \alpha_0 \tan \delta_0 \\
c &= \tfrac{1}{15} \cos \alpha_0 \sec \delta_0 \\
d &= \tfrac{1}{15} \sin \alpha_0 \sec \delta_0 \\
a' &= 20''.0526 \cos \alpha_0 = \text{precession in declination} \\
b' &= - \sin \alpha_0 \\
c' &= \tan \omega \cos \delta_0 - \sin \alpha_0 \sin \delta_0 \\
d' &= \cos \alpha_0 \sin \delta_0
\end{aligned}$$

**Reduction to Apparent Position.**

$$\begin{aligned}
a &= \alpha_0 + \tau \mu + Aa + Bb + Cc + Dd + \tfrac{1}{15} E && \text{(in time)} \\
\delta &= \delta_0 + \tau \mu' + Aa' + Bb' + Cc' + Dd' && \text{(in arc)}
\end{aligned}$$

**INDEPENDENT STAR-NUMBERS.**

$$\begin{aligned}
f &= 46''.0891 A + E \text{ (in arc)} = 3^\circ 07261 A + \tfrac{1}{15} E \text{ (in time)} \\
g \sin G &= B & h \sin H &= C & i &= C \tan \omega \\
g \cos G &= 20''.0526 A & h \cos H &= D
\end{aligned}$$

**Reduction to Apparent Position.**

$$\begin{aligned}
a &= \alpha_0 + f + \tau \mu + \tfrac{1}{15} g \sin (G + \alpha_0) \tan \delta_0 + \tfrac{1}{15} h \sin (H + \alpha_0) \sec \delta_0 && \text{(in time)} \\
\delta &= \delta_0 + \tau \mu' + g \cos (G + \alpha_0) + h \cos (H + \alpha_0) \sin \delta_0 + i \cos \delta_0 && \text{(in arc)}
\end{aligned}$$

NOTES.—(1) The independent star-numbers are more convenient, when only one or two apparent positions of a star are required, or when Bessel's star-constants are not known with sufficient accuracy. Otherwise, the Besselian star-numbers are more convenient.

(2) In using the star-constants of the *British Association Catalogue*,  $a, b, c, d, a', b', c', d'$ , must be changed to  $c, d, a, b, -c', -d', -a', -b'$ , respectively.

*PART III*

---

**PHENOMENA**

## ECLIPSES, 1894.

## ECLIPSES IN 1894.

In the year 1894 there will be four eclipses: two of the sun and two of the moon.

I.—*A partial Eclipse of the Moon*, 1894, March 20—21, invisible at Washington; the beginning visible in the extreme west portion of North America, the Pacific Ocean, and Asia, except the extreme west portion; the end visible in Alaska, the Pacific Ocean and all of Asia.

## ELEMENTS OF THE ECLIPSE.

Greenwich mean time of 8 in right ascension, March 21	<sup>d</sup>	<sup>h</sup>	<sup>m</sup>	<sup>s</sup>	
Sun's right ascension	0	3	24.38	Hourly motion	9.10
Moon's right ascension	12	3	24.38	Hourly motion	120.73
Sun's declination	0	22'	10".1	Hourly motion	0 59'.2 N.
Moon's declination	0	36	9.5	Hourly motion	16 29.3 S.
Sun's equa. hor. parallax		8.6		Sun's semidiameter	16 2.9
Moon's equa. hor. parallax	58	10.5		Moon's semidiameter	15 50.4

## TIMES OF THE PHASES.

Moon enters penumbra	March 20	<sup>d</sup>	<sup>h</sup>	<sup>m</sup>	Greenwich Mean Time.
Moon enters shadow		23	57.4		
Middle of the eclipse		21	1	25.3	
Moon leaves shadow		21	2	20.6	
Moon leaves penumbra		21	3	15.7	
		21	4	43.7	

## CIRCUMSTANCES OF THE ECLIPSE.

Contacts of Shadow with moon's limb.	Angles of position from north point.	The moon being in the zenith in longitude from Greenwich	and in latitude.
First	179° to E.	160° 28' E.	0° 37' N.
Last	121° to W.	133° 42' E.	0° 7 N.

Magnitude of the eclipse = 0.248, (moon's diameter = 1).

II.—*An Annular Eclipse of the Sun*, 1894, April 5, invisible at Washington.

## ELEMENTS OF THE ECLIPSE.

Greenwich mean time of 6 in right ascension, April 5	<sup>d</sup>	<sup>h</sup>	<sup>m</sup>	<sup>s</sup>	
Sun and moon's R. A.	1	0	16.90	Hourly motions	9.14 and 121.28
Sun's declination	6	26	11.6	Hourly motion	0 56.7 N.
Moon's declination	7	3	48.5	Hourly motion	15 53.7 N.
Sun's equa. hor. parallax		8.6		Sun's true semidiameter	15 58.6
Moon's equa. hor. parallax	57	52.5		Moon's true semidiameter	15 45.5

## CIRCUMSTANCES OF THE ECLIPSE.

Eclipse begins	April	<sup>d</sup>	<sup>h</sup>	<sup>m</sup>	Longitude from Greenwich.	Latitude.
Central eclipse begins		5	13	15.9	72° 24.2' E.	6 33.6 S.
Central eclipse at noon		5	14	24.0	53 41.8 E.	6 47.4 N.
Central eclipse ends		5	16	27.7	113 42.5 E.	47 22.3 N.
Eclipse ends		5	17	23.3	157 30.7 W.	62 47.5 N.
		5	18	31.5	179 34.2 W.	49 44.5 N.

III.—*A Partial Eclipse of the Moon, 1894, September 14, visible at Washington; the beginning visible generally in the western portions of Europe and Africa, the Atlantic Ocean, North and South America, and the eastern portion of the Pacific Ocean; the end visible generally in the extreme west portion of Africa, the Atlantic Ocean, North and South America, and the eastern part of the Pacific Ocean.*

*ELEMENTS OF THE ECLIPSE.*

	Greenwich mean time of $\delta$ in right ascension, September 14	$d\ h\ m\ s$	
Sun's right ascension	11 31 36.20		Hourly motion 8.97
Moon's right ascension	23 31 36.20		Hourly motion 109.98
Sun's declination	$3^{\circ} 4' 10.0''$ N.		Hourly motion $0^{\circ} 57.8'$ S.
Moon's declination	$3^{\circ} 59' 33.5''$ S.		Hourly motion 14 52.6 N.
Sun's equa. hor. parallax	8.5		Sun's true semidiameter 15 54.9
Moon's equa. hor. parallax	55 24.1		Moon's true semidiameter 15 5.0

*TIMES OF THE PHASES.*

	September	$d\ h\ m$	
Moon enters penumbra	14 13 58.6		
Moon enters shadow	14 15 35.6		
Middle of the eclipse	14 16 31.6		
Moon leaves shadow	14 17 27.7		
Moon leaves penumbra	14 19 4.4		

*CIRCUMSTANCES OF THE ECLIPSE.*

Contacts of Shadow with moon's limb.	Angles of position from north point.	The moon being in the zenith in longitude from Greenwich	and in latitude.
First	$0^{\circ}$	$55^{\circ} 5' W.$	$4^{\circ} 0' S.$
Last	58 to W.	82 21 W.	3 32 S.

Magnitude of the eclipse = 0.231, (moon's diameter = 1).

IV.—*A Total Eclipse of the Sun, 1894, September 28, invisible at Washington.**ELEMENTS OF THE ECLIPSE.*

	Greenwich mean time of $\delta$ in right ascension, September 28	$d\ h\ m\ s$	
Sun and moon's R. A.	12 22 19.38		Hourly motions 9.04 and 124.53
Sun's declination	$2^{\circ} 24' 58.3''$ S.		Hourly motion $0^{\circ} 58.4''$ S.
Moon's declination	2 55 48.6 S.		Hourly motion 16 57.0 S.
Sun's equa. hor. parallax	8.6		Sun's true semidiameter 15 58.6
Moon's equa. hor. parallax	59 3.6		Moon's true semidiameter 16 4.8

*CIRCUMSTANCES OF THE ECLIPSE.*

	September	$d\ h\ m$	Longitude from Greenwich.	Latitude.
Eclipse begins	28 15 1.0		$42^{\circ} 50.7' E.$	$11^{\circ} 49.2' N.$
Central eclipse begins	28 16 3.7		26 44.3 E.	1 47.1 N.
Eclipse at noon	28 18 6.2		86 13 E.	34 11.6 S.
Central eclipse ends	28 19 14.1		162 43.3 E.	56 24.9 S.
Eclipse ends	28 20 17.0		145 54.0 E.	46 24.1 S.

The regions within which the eclipses of the sun are visible, are laid down on the accompanying charts; from which, by means of the dotted lines, may also be found the Greenwich time of beginning and ending, within fifteen or twenty minutes.

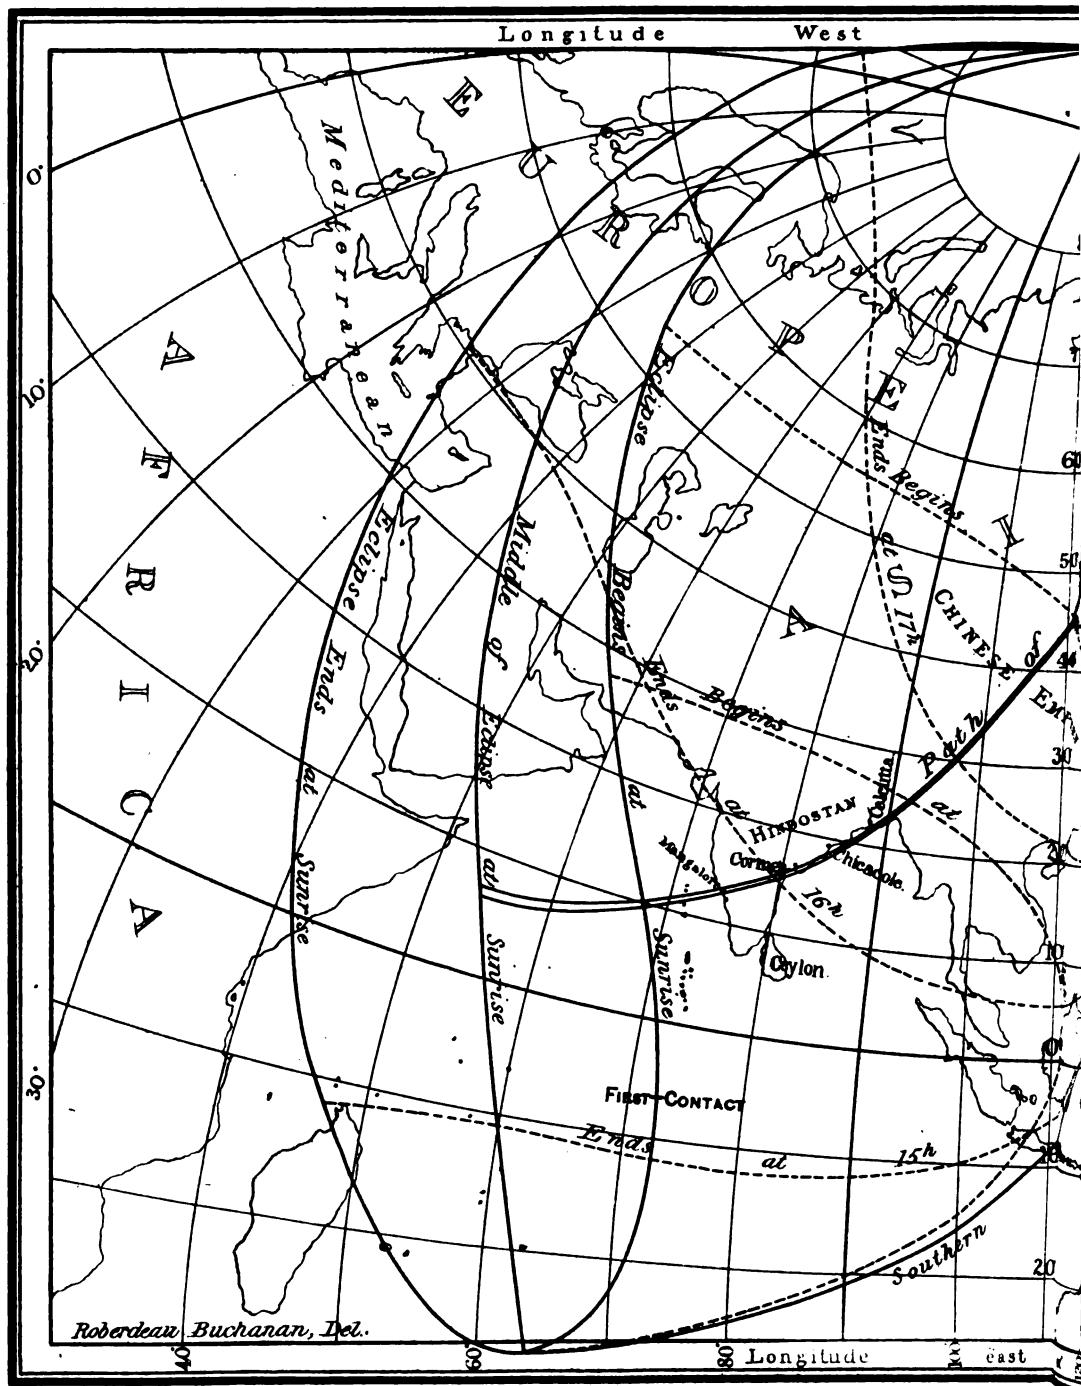

## ECLIPSES, 1894.

BESSELIAN ELEMENTS OF THE ANNULAR ECLIPSE  
OF THE SUN, 1894, APRIL 5.

Greenwich Mean Time.  h m	Co-ordinates of Centre of Shadow on Fundamental Plane.		Direction of Axis of Shadow.			Radius of Penumbra and Shadow on Fundamental Plane.

## TRANSIT OF MERCURY, 1894.

*A Transit of Mercury, 1894.*—A Transit of Mercury over the Sun's Disk, November 10, visible at Washington, and visible generally in the western portions of Europe, in Africa, North and South America, and the Pacific Ocean.

## ELEMENTS OF THE TRANSIT.

	d h m s
Greenwich mean time of $\delta$ in right ascension, November 10	6 54 16.3
Sun and Mercury's R. A. $\overset{h}{15} \overset{m}{3} \overset{s}{44.68}$	Hourly motions      + 10.12 and — 12.46
Sun's declination $\overset{\circ}{17} \overset{'}{18} \overset{''}{58.2}$ S.	Hourly motion $\overset{''}{0} \overset{'}{41.8}$ S.
Mercury's declination $\overset{\circ}{17} \overset{'}{14} \overset{''}{5.2}$ S.	Hourly motion $\overset{\circ}{1} \overset{'}{45.2}$ N.
Sun's equa. hor. parallax      8.94	True semidiameter $\overset{\circ}{16} \overset{'}{9.83}$
Mercury's equa. hor. parallax      13.08	True semidiameter      4.94

## TIMES OF THE PHASES.

Ingress, exterior contact	November 10	$d^{\circ} h' m'' s$	Greenwich Mean Time.
Ingress, interior contact	10	$3^{\circ} 57' 15.4$	
Least distance of centres $4' 26''.8$	10	$6^{\circ} 33' 48.5$	
Egress, interior contact	10	$9^{\circ} 10' 26.4$	
Egress, exterior contact	10	$9^{\circ} 12' 10.4$	

## CIRCUMSTANCES OF THE TRANSIT.

Exterior contacts.	Angles of position from north point.	The sun being in the zenith, in longitude from Greenwich	and in latitude.
Ingress	$98^{\circ} 32'$ toward East.	$62^{\circ} 35'$ W.	$17^{\circ} 17'$ S.
Egress	$49^{\circ} 41'$ toward West.	$142^{\circ} 14'$ W.	$17^{\circ} 21'$ S.

The Greenwich mean time of exterior contacts, for any point on the surface of the earth, may be computed from the following formulæ, in which  $\rho$  denotes the radius of the earth at the place,  $\phi$  the geocentric north latitude and  $\lambda$  the longitude *west* from Greenwich.

$$\begin{aligned} \text{Ingress } T' &= 3^{\circ} 55' 31.2 + [0.7793] \rho \sin \phi - [1.6352] \rho \cos \phi \cos (329^{\circ} 28' 15'' - \lambda) \\ \text{Egress } T' &= 9^{\circ} 12' 10.4 + [1.4333] \rho \sin \phi + [1.5339] \rho \cos \phi \cos (218^{\circ} 51' 7'' - \lambda) \end{aligned}$$

## WASHINGTON MEAN TIME.

## PHASES OF THE MOON.

New Moon.	First Quarter.	Full Moon.	Last Quarter.

May 23 7.2	June 4 12.6	May 29 15 29 E.	June 11 0 50 W.			
June 19 17.7	July 2 20.6	June 26 19 41 E.	July 9 23 54 W.			
July 16 21.4	July 31 6.0	July 24 23 31 E.	August 6 4 10 W.			
August 13 2.4	August 28 13.5	August 21 20 26 E.	September 3 8 5 W.			
September 9 15.1	September 25 12.4	September 17 19 6 E.	October 1 7 8 W.			
October 7 8.7	October 21 20.5	October 14 0 45 E.	October 28 18 16 W.			
November 4 4.9	November 16 3.5	November 10 5 26 E.	November 24 4 56 W.			
December 2 5.9	December 13 21.9	December 8 3 17 E.	December 20 17 7 W.			
December 29 18.2						

## FORMULÆ FOR THE LIBRATION OF THE MOON.

Put  $I$ , the inclination of the moon's equator to the ecliptic ( $= 1^\circ 28' 8''$ ),

$\Omega$ , the mean longitude of the moon's ascending node, (see page 278), or the mean longitude of the descending node of the moon's equator,

$C$ , the angle at the centre of the moon's disk made by a lunar meridian with the circle of declination, counted from north to east on the apparent disk,

$\lambda, \beta, \alpha', \delta'$ , the apparent longitude, latitude, right ascension, and declination of the moon, corrected for parallax,

$\lambda'$ , the selenocentric longitude of the earth, counted on the moon's equator from its descending node,  $\Omega$ ,

$i, \Delta, \Omega', \zeta$ , the quantities defined on page 276, where their values for the year are given.

The moon's libration in longitude and latitude may then be found, for any time, by means of the following formulæ, in connection with the tables given on pages 276 and 277:—

$$\begin{aligned} \Delta \lambda &= -0'.57 \sin 2(\Omega - \lambda) \\ a &= \sin I \cos (\Omega - \lambda) \\ \tan B &= \tan I \sin (\Omega - \lambda) \end{aligned} \quad \left. \begin{aligned} \lambda' &= \lambda + \Delta \lambda + a b \\ \text{The libration in latitude } &= b = B - \beta \\ \text{The libration in longitude } &= l = \lambda' - \zeta \end{aligned} \right\} \text{See table, page 277.}$$

$$\begin{aligned} \sin C &= \sin i \frac{\cos (\lambda' + \Delta - \Omega)}{\cos \delta'} = -\sin i \frac{\cos (\alpha' - \Omega')}{\cos b} \end{aligned}$$

<i>NEW MOON.</i>													

Note.—The angles of position are counted from the north point and vertex of the moon's limb, toward the east.

• Whole occultation below the horizon of Washington.

† Immersion below the horizon of Washington.

‡ Emersion below the horizon of Washington.

## PREDICTION OF OCCULTATIONS.

## NOTATION.

*k*, the ratio of the illuminated portion of the apparent disk to the entire apparent disk considered as the superficies of a circle.

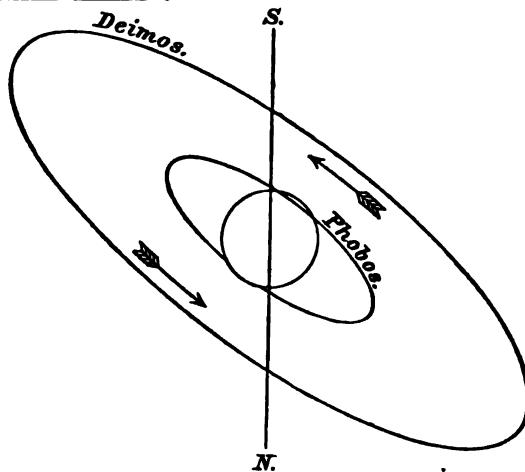

*i*, the angle between the sun and earth, as seen from the planet.

$\theta$ , the angle which the line joining the cusps, or extremities of the illuminated portion, makes with the meridian.

*L*, the brilliancy of the disk. The unit of *L* is the amount of light received by an eye from a circular disk with the same albedo as the planet, subtending an angular radius of one second of arc, situated at distance unity from the sun, and illuminated by the latter as the mean disk of the planet is illuminated.

APPARENT ORBITS OF THE SATELLITES OF MARS DURING THE OPPOSITION OF 1894,  
AS SEEN IN AN INVERTING TELESCOPE.

The circle represents the disk of the planet and is on the same scale as the orbits. The mean motions of the satellites have been corrected by the observations made during the oppositions of 1888 and 1890.

For Phobos every seventh eastern and western elongation is given, and for Deimos every third; the intermediate ones may be found by adding the periodic time of each satellite.

Periodic time of Phobos,  $0^d 7^h 39^m 13.937$ . Periodic time of Deimos,  $1^d 6^h 17^m 54.377$ .

APPARENT DISK OF MARS.

May 1,	0.863				

The numbers in this table are the versed sines of the illuminated disk, the apparent diameter of the planet being taken as unity.

*APPARENT ORBITS OF THE SATELLITES OF JUPITER IN 1894,  
AS SEEN IN AN INVERTING TELESCOPE.*

*(THE VERTICAL SCALE IS THREE TIMES THE HORIZONTAL ONE.)*

The object of this figure is to facilitate the identification of the satellites in cases where the diagrams of configurations do not suffice for that purpose: reference to the above diagram enables one to identify the inner and outer satellite of the pair. The central, vertical ellipse represents the disk of Jupiter, elongated three times in the vertical direction to correspond to the representation of the orbits of the satellites.

Facing each page of the phenomena of Jupiter's satellites, pages 460—480, is the page of diagrams of configurations, for the same month. The light disks ○ in the vertical row in the middle of the page represent the relative position of Jupiter each day. The dots adjacent in the same horizontal space represent the positions of the several satellites on the same day, at the hour and minute of Washington mean time indicated above the diagrams. The latitudes of the satellites are always considered zero in constructing the diagrams, except where two or more satellites chance to be at nearly the same distance from the planet, when they are placed one above the other according to their apparent latitudes. The numerals designating the satellites are placed on the right or left hand side of the dot, according as the motion of the satellite, for the time of the configuration, is toward the east or toward the west—the motion being always toward the numeral. Frequently, at the epoch of the configuration, one or more satellites will be invisible, being projected on the disk of the planet: this phenomenon is indicated by a light disk ○ at the left hand side of the page. Frequently, also, one or more satellites will be invisible, being concealed in occultation behind the disk, or eclipsed in the shadow of the planet: this phenomenon is indicated by a dark disk ● at the right hand side of the page. In both cases, the annexed numeral serves to point out which satellite is thus rendered invisible.

When an observation is made at a different hour from that for which the diagram is constructed, the motion of the satellite during the interval may be judged by transferring its given position to the above diagram, and estimating its motion during the elapsed interval on the above diagram of the orbits, by means of the following table of the periods:—

#### MEAN SYNODIC PERIODS OF THE SATELLITES.

	d	h	m	s	=	d
I.	1	18	28	35.945	=	1.76986048
II.	3	13	17	53.735	=	3.55409416
III.	7	3	59	35.854	=	7.16638720
IV.	16	18	5	6.928	=	16.75355241

## THE SATELLITES OF JUPITER

ARE INVISIBLE FROM MAY 8TH UNTIL JULY 1ST,

JUPITER BEING TOO NEAR THE SUN

NOTE.—In. denotes ingress; Eg., egress; Dis., disappearance; Re., reappearance; Ec., eclipse.

Oc. denotes occultation; Tr., transit of the satellite; Sh., transit of the shadow; \* Visible at Washington.

## WASHINGTON MEAN TIME OF GREATEST ELONGATION, ETC.

In the diagram on the preceding page, the points of the orbits marked "o" are those of the eastern elongation, as seen in an inverting telescope. The apparent positions of a satellite at any time may be marked on the diagram by counting around the orbit the interval in days and hours which has elapsed since the last east elongation. The times of these elongations may be found from the following tables. Mimas can be seen only within a few hours of each elongation: the time of every elongation visible at Washington is therefore given. The times of other elongations of any satellite in the same direction may be found by adding or subtracting any multiple of the period. For the three outer satellites the times of elongation and conjunction are given. The following abbreviations are used:—

E., East Elongation,  
 L., Inferior Conjunction (south of planet),  
 W., West Elongation,  
 S., Superior Conjunction (north of planet).

Period of Ariel, 2 12.489  
Period of Umbriel, 4 3.460

Period of Titania, 8 16.942  
Period of Oberon, 13 11.119

NOTE.—For Ariel only every third elongation is given, and for Umbriel every alternate one. The intermediate ones may be found by adding multiples of the period of the satellite.

10 12.2	7 13.8	25 14.7	28 13.2	4 3.9	

The above times are those of each passage of the satellite through an apsis of its apparent orbit. The position of the satellite at any other time may be found by measuring around the orbit from the apsis last passed through, remembering that the radius vector of the satellite describes equal areas in equal times.

Period of the satellite of Neptune, 5<sup>4</sup> 21<sup>b</sup>.045.

**Note.**—In the preceding diagrams the central circle represents the planet, and is on the same scale as the orbits.

## ON THE ARRANGEMENT AND USE OF THE AMERICAN EPHEMERIS AND NAUTICAL ALMANAC.

---

### PART I—THE EPHEMERIS FOR THE MERIDIAN OF GREENWICH.

THE greater portion of this Ephemeris, embracing the positions of the sun and moon; the distances of the moon from the centres of the sun and the four most conspicuous planets, and from certain fixed stars; the ephemerides of the planets Mercury, Venus, Mars, Jupiter, and Saturn, is designed for the special use of navigators. The remainder contains the ephemerides of Uranus and Neptune, the heliocentric co-ordinates of the seven major planets, the rectangular equatorial co-ordinates of the sun, the moon's longitude and latitude, data for the libration of the moon, the obliquity of the ecliptic, the equation of the equinoxes, etc.

#### TIME.

Astronomers make use of several different kinds of time; mean solar time; true, or apparent solar time; and sidereal time.

*Solar Time.*—Solar time is that used for all the purposes of ordinary life, and is measured by the daily motion of the sun. A *Solar Day* is the interval of time between two successive transits of the sun over the same meridian; and the hour-angle of the sun is called *Solar Time*. This is the most natural and direct measure of time. But the intervals between the successive returns of the sun to the same meridian are not exactly equal, owing to the varying motion of the earth around the sun, and to the obliquity of the ecliptic. The intervals between the sun's transits over the meridian being unequal it is impossible to regulate a clock or chronometer so that it shall accurately follow the sun.

To avoid the irregularity which would arise from using the true sun as the measure of time, a fictitious sun, called the *Mean Sun*, is supposed to move in the equator with a uniform velocity. This mean sun is supposed to keep, on the average, as near the real sun as is consistent with perfect uniformity of motion; it is sometimes in advance of it, and sometimes behind it, the greatest deviation being about 16 minutes of time.

*Mean Solar Time*, which is perfectly equable in its increase, is measured by the motion of this mean sun. The clocks in ordinary use and the chronometers used by navigators are regulated to mean solar time.

*True, or Apparent Solar Time* is measured by the motion of the real sun.

The difference between apparent and mean time is called the *Equation of Time*. By means of it, we change apparent to mean time, or the reverse. Thus, if the apparent time be given, the mean time corresponding to it will be obtained by adding or subtracting the equation of time, according to the precept at the head of the column in which it is found, on page I of the Calendar for each month. If the mean time be given, the apparent time is obtained by applying the equation of time as directed by the precept on page II of the Calendar.

*Sidereal Time.*—Sidereal time is measured by the daily motion of the stars; or, as it is used by astronomers, by the daily motion of that point in the equator from which the true right ascension of the stars is counted. This point is the vernal equinox, and its hour-angle is called *Sidereal Time*. Astronomical clocks, regulated to sidereal time, are called sidereal clocks.

A *Sidereal Day* is the interval of time between the transit of the vernal equinox over the meridian, and its next succeeding return to the same meridian. It is about 3<sup>m</sup> 56<sup>s</sup> shorter than the mean solar day; 365½ solar days, or a year, being divided into 366½ sidereal days. It is divided into 24 hours. The sidereal hours are counted from 0 to 24, commencing with the instant of the passage of the true vernal equinox over the upper meridian, and ending with its return to the same meridian. About March 21st of each year the sidereal clock agrees with the mean time, or ordinary clock, and the former gains on the latter about 3<sup>m</sup> 56<sup>s</sup> per day, so that at the end of a year it will have gained an entire day, and will again agree with the mean time clock.

*Day*.—The *Civil Day*, according to the customs of society, commences at midnight, and comprises twenty-four hours, from one midnight to the next following. The hours are counted from 0 to 12 from midnight to noon, after which they are again reckoned from 0 to 12 from noon to midnight. Thus the day is divided into two periods of 12 hours each, of which the first is marked A. M., and the last is marked P. M.

The *Astronomical Day* commences at noon on the civil day of the same date. It also comprises twenty-four hours, but they are reckoned from 0 to 24, and from the noon of one day to that of the next following. The astronomical as well as the civil time may be either apparent or mean, according as it is reckoned from apparent noon or from mean noon.

The civil day begins twelve hours before the astronomical day; therefore the first period of the civil day answers to the last part of the preceding astronomical day, and the last period of the civil day corresponds to the first part of the same astronomical day. Thus, January 9th, 2 o'clock, A. M., civil time, is January 8th, 14<sup>h</sup>, astronomical time; and January 9th, 2 o'clock, P. M., civil time, is also January 9th, 2<sup>h</sup>, astronomical time. The rule, then, for the transformation of civil time into astronomical time is this:—*If the civil time is marked A. M., take one from the day and add twelve to the hours, and the result is the astronomical time wanted; if the civil time is marked P. M., take away the designation P. M., and the astronomical time is had without further change.*

*To change astronomical to civil time, we simply write P. M. after it, if it is less than 12 hours. If greater than 12 hours, we subtract 12 hours from it, add 1 to the days, and write A. M.* For example, January 3d, 23 hours, astronomical time, is January 4th, 11 o'clock, A. M., civil time.

If the longitude from Greenwich be expressed in time, and, when *west*, *added* to the local time, or, when *east*, *subtracted* from the local time, the result is the corresponding Greenwich time. If the local mean time is used, the result is the Greenwich mean time, which ordinarily is that required for the use of this Ephemeris. The rule is the same, whether we use mean or sidereal time.

#### THE CALENDAR.

The Calendar is divided into twelve months, and to each month are assigned eighteen pages, the contents of which are as follow:—

Page I contains, for Greenwich apparent noon of each day, *The Sun's Apparent Right Ascension* and *Declination*, and the *Equation of Time*. Adjoining columns contain the differences of these quantities for one hour. By multiplying this difference by the hours and parts of an hour from Greenwich apparent noon, and adding the amount to, or subtracting it from, the quantity at noon, according as that quantity is increasing or decreasing, we obtain the value of any quantity for any given Greenwich apparent time. The hourly differences are given for the instant of apparent noon at Greenwich, and, when greater accuracy is required, should be first interpolated for half the hours and parts of an hour of the Greenwich apparent time.

This page is chiefly used when the sun is observed on the meridian, and the local apparent time is 0<sup>h</sup> 0<sup>m</sup> 0<sup>s</sup>. The longitude from Greenwich expressed in time, if west, is at that instant the Greenwich apparent time, or time after Greenwich apparent noon; if east, it is time before

Greenwich apparent noon. The longitude of any place is therefore employed in reducing the quantities on this page to apparent noon at the place.

The right ascension of the sun thus reduced is the sidereal time of local apparent noon. The difference between it and the clock time of the meridian passage of the sun is the error of the clock on sidereal time.

The declination of the sun reduced to the meridian, or apparent noon, of the place, is required in finding the latitude from a meridian altitude of the sun.

As an example of the use of page I:—

Let the sun's declination be required at apparent noon, 1894, May 31, at a place whose longitude is  $179^{\circ} 40'$ , or  $11^{\text{h}} 58^{\text{m}} 40^{\text{s}}$  east from Greenwich:

Local apparent time . . . .	May 31,	<sup>h</sup>	<sup>m</sup>	<sup>s</sup>
Longitude from Greenwich (subtractive) . . . .		11	58	40
Greenwich apparent time . . . .	May 30,	12	1	20

Reducing the minutes and seconds to decimals of an hour, we find that this moment is  $12^{\text{h}}.022$  after Greenwich apparent noon on May 30, or  $11^{\text{h}}.978$  before Greenwich apparent noon on May 31.

On page 74 of the Ephemeris we find that the change of declination in one hour is

May 30, at Greenwich apparent noon . . . .	<u>22.09</u>
May 31, at Greenwich apparent noon . . . .	<u>21.14</u>
Difference for one day . . . .	0.95

If we want to be very exact, we find the amount of this hourly difference for the time which is half way between Greenwich noon and the time of observation; that is, for 6 hours after Greenwich noon of the 30th, this being half of 12 hours. Six hours is 0.25 of a day; so the calculation is as follows:—

Difference for one hour, May 30 . . . .	<u>22.09</u>
Change for 0.25 of a day or $0''.95 \times 0.25$ . . . .	<u>0.24</u>
Difference at 6 hours after noon . . . .	<u>21.85</u>
$21''.85 \times 12.022 = 262''.7 = 4' 22''.7$	
Declination at Greenwich noon, May 30 . . . .	N. $21^{\circ} 48' 56''.7$
Change in 12.022 hours (additive) . . . .	<u>4 22.7</u>
Sun's declination at time of observation . . . .	N. $21^{\circ} 53' 19.4$

When the time of observation is only a few hours before Greenwich noon, it may be better to count the longitude backward from this nearest noon. Thus, in the example just given, the time is  $11^{\text{h}}.978$  before Greenwich noon of May 31; half this interval is about 0.25 of a day, and the hourly motion for the middle of the interval is  $21''.38$ . Then, we find:—

Declination at Greenwich noon, May 31 . . . .	N. $21^{\circ} 57' 35''$
Product of $21''.38 \times 11.978 = 256''.1$ (subtractive) . . . .	<u>4 16.1</u>
Sun's declination at time of observation . . . .	N. $21^{\circ} 53' 19.4$

It will always be well to make the calculation by both methods, as their agreement will show both to be right.

At sea it is ordinarily sufficient to have the declination to the nearest half minute, and the reduction may be found by Table V of BOWDITCH'S *American Practical Navigator*.

The equation of time, as has been before explained, is the number of minutes and seconds to be added to or subtracted from the apparent time, or the time given by an observation of the sun, to obtain the mean time. The heading of the column directs the manner in which the equation is to be applied. When there is a change in the course of the month from addition to subtraction or the reverse (as in the months of April and June), the two different directions are separated by a line, while a corresponding line below points out the dates between which the change takes place. The equation of time, as given on page I, is the mean time of apparent noon, or the hour-angle of the mean sun at that instant.

*The Sun's Semidiameter* and the *Sidereal Time of Semidiameter Passing Meridian* are also given on page I. The sun's semidiameter is used in reducing the altitude of the upper or lower limb of the sun to the altitude of the center; and in reducing the angular distance of the limb from the moon or some other object, to the distance from the center of the sun. The sidereal time of semidiameter passing the meridian is employed in obtaining the passage of the sun's center over the wires of a transit-instrument, when the passage of one limb only has been observed. The quantity found in this column is to be added to the time of transit of the first, or western, limb; and to be subtracted from the time of transit of the second, or eastern, limb.

Page II contains, for Greenwich mean noon of each day, *The Sun's Apparent Right Ascension*, and *Declination*, the *Equation of Time*, and the *Sidereal Time of Mean Noon*. The hourly changes of these quantities are also given, and may be used in reducing them to any Greenwich mean time. The hourly changes may be first interpolated for half the Greenwich time, when great precision is required, in the way described in explaining the calculation of the declination.

The right ascension and declination on pages I and II are affected by aberration, and therefore denote the *apparent* position of the *true* sun. Page II is more conveniently used when the mean time is known. This is the case in most observations of the sun out of the meridian, when the times have been noted by a clock or chronometer regulated to mean time. The quantities on this page can be reduced to mean noon of any place by interpolating for the longitude, as in the example of the sun's declination on the preceding page.

The sun's declination is required for finding the latitude of the place, the local time, and the sun's azimuth and amplitude, from observations of the sun.

The equation of time is needed in finding the mean time from observations of the sun, and the latitude from observations out of the meridian. The heading of the column directs the manner in which it is to be applied to mean time to obtain the apparent time.

The equation of time, as given on page II, is the apparent time of mean noon; and is equivalent to the hour-angle of the true sun at the instant of mean noon.

The sidereal time of mean noon is also the right ascension of the mean sun at Greenwich mean noon. It may be reduced for the longitude, or to any Greenwich mean time, by using the hourly difference, 9°.8565; or by Table III, appended to this volume, for reducing intervals of mean solar to sidereal time. Table LI of Bowditch's *Navigator* may be used for the same purpose when only the nearest quarter of a second is required.

The sun's right ascension and the sidereal time of mean noon, or right ascension of the mean sun, are useful in converting mean time to sidereal time. We first find the Greenwich mean time, then the R. A. of the mean sun for this time, as last explained: this being added to the local mean time will give the sidereal time.

The sidereal time of mean noon, reduced for the longitude of the place, is also used in converting sidereal time to mean time. Subtracting the reduced value from the given sidereal time, gives the interval of sidereal time from noon. Subtracting from this the corresponding reduction of a sidereal interval to a mean time interval, in Table II, appended to this volume, or Table LII of Bowditch's *Navigator*, will give the mean time required. This reduction may also be found by multiplying 9.8296 by the hours and parts of an hour of the given sidereal time.

As examples of the use of page II:—

1.—Let the sun's right ascension and the equation of time be required for 1894, May 15, 9<sup>h</sup> 2<sup>m</sup> 30<sup>s</sup>, A. M., mean time, at a place whose longitude is 100° 10', or 6<sup>h</sup> 40<sup>m</sup> 40<sup>s</sup>, west of Greenwich.

Local astronomical mean time . . . .	May 14,	21	2	30	6
Longitude from Greenwich (additive) . . . .	.	6	40	40	
Greenwich mean time . . . .	May 15,	3	43	10	= 3 <sup>h</sup> .7194

	Sun's Right Ascension.	Equation of Time.
May 15, Greenwich noon .	$3^{\text{h}} 28^{\text{m}} 57.30$	$3^{\text{m}} 50.48$ (additive)
H. D. $9^{\circ}.878 \times 3.7194$ . . + 0 36.74		H. D. $-0.024 \times 3.72$ — 0.09
	$3^{\text{h}} 29^{\text{m}} 34.04$	$3^{\text{m}} 50.39$

In this case, the hourly differences interpolated to half the interval, or  $1^{\text{h}}.9$  after noon, have been used.

The equation of time in this example is additive to mean time. Its reduction could also have been found by Table VI, A<sup>c</sup>, of BOWDITCH'S *Navigator*, but to seconds only.

2.—If the sidereal time is required for the same date and time, we have:—

	$\text{h m s}$
May 15, Sidereal Time (at Greenwich mean noon) . . . .	$3^{\text{h}} 32^{\text{m}} 47.78$
Hourly difference $9^{\circ}.8565 \times 3.7194$ . . . . . + 0 36.66	
Add the local astronomical mean time . . . . .	$21^{\text{h}} 2^{\text{m}} 30.00$
The required sidereal time is (rejecting $24^{\text{h}}$ ) . . . . .	$0^{\text{m}} 35^{\text{s}} 54.44$

The reduction  $0^{\text{m}} 36^{\text{s}}.66$  could have been found in Table III corresponding to the Greenwich mean time  $3^{\text{h}} 43^{\text{m}} 10^{\text{s}}$ . Also, by Table LI of BOWDITCH'S *Navigator*, the reduction is  $0^{\text{m}} 36^{\text{s}}.7$ .

3.—On 1894, May 15, A. M., at a place whose longitude is  $100^{\circ} 10' \text{W.}$ , suppose the sidereal time to be  $0^{\text{h}} 36^{\text{m}} 37^{\text{s}}.16$ , and that the corresponding mean time is required.

The astronomical day is May 14; the longitude in time,  $+6^{\text{h}} 40^{\text{m}} 40^{\text{s}}$ , or  $+6^{\text{h}}.678$ .

	$\text{h m s}$
May 14, Sidereal Time (at Greenwich mean noon) . . . .	$3^{\text{h}} 28^{\text{m}} 51.23$
The H. D. $9^{\circ}.8565 \times 6.678$ , or the reduction for $6^{\text{h}} 40^{\text{m}} 40^{\text{s}}$ in Table III . . . + 1 5.82	
The sidereal time of local mean noon . . . . .	$3^{\text{h}} 29^{\text{m}} 57.05$
The given sidereal time (+24 <sup>h</sup> , if necessary for the following subtraction) . . . . .	$24^{\text{h}} 36^{\text{m}} 37.16$
Subtracting the first from the second gives the sidereal interval from noon . . . . .	$21^{\text{h}} 6^{\text{m}} 40.11 = 21^{\text{h}}.1114$
— $9^{\circ}.8296 \times 21.1114$ , or the reduction for $21^{\text{h}} 6^{\text{m}} 40.11$ in Table II . . . . .	$— 3^{\text{m}} 27.51$
The required astronomical mean time is . . . . .	May 14, $21^{\text{h}} 3^{\text{m}} 12.60$

Page III contains, for Greenwich mean noon of each day, *The Sun's True Longitude and Latitude*, and the *Logarithm of the Radius Vector of the Earth*. The longitudes of the sun are the true longitudes, not corrected for aberration. The longitude is given in two columns, headed  $\lambda$  and  $\lambda'$ ;  $\lambda$  representing the sun's longitude counted from the true equinox of the date; and  $\lambda'$ , the same co-ordinate counted from the mean equinox of the beginning of the year, (January 0<sup>d.0</sup>). A column of hourly differences enables the computer to obtain the sun's longitude for any hour from noon. The hourly differences of the logarithm of the radius vector are likewise given. The latitude is referred to the ecliptic of the date.

The last column on page III contains the *Mean Time of Sidereal Noon*; that is, the number of hours, minutes and seconds after Greenwich mean noon when the first point of Aries passes the meridian of Greenwich. It may be reduced to any meridian by interpolating for the longitude, or to any Greenwich sidereal time by means of the hourly difference,  $-9^{\circ}.8296$ . The reduction, however, can be taken directly from Table II for reducing intervals of sidereal time to mean solar time; or, approximately, from Table LII of BOWDITCH'S *Navigator*.

This column may be used in converting sidereal time to mean time instead of that on page II. As an illustration, let us take Example 3, above.

It is seen in advance that the sum of the mean time of sidereal noon and the given sidereal time is less than 24 hours. Were it more than 24 hours, the mean time of sidereal noon should be taken out for May 13, that is the preceding astronomical day.

May 14, the mean time of Greenwich sidereal noon is . . . .	$20^{\text{h}} 27^{\text{m}} 47.08$
The H. D. $-9^{\circ}.8296 \times 6.678$ , or the reduction for long., Table II . . . . .	$— 1^{\text{h}} 5.64$
The mean time of local sidereal noon . . . . .	$20^{\text{h}} 26^{\text{m}} 41.44$
Add the given sidereal time . . . . .	$0^{\text{m}} 36^{\text{s}} 37.16 = 0^{\text{h}}.6103$
The sum is . . . . .	$21^{\text{h}} 3^{\text{m}} 18.60$
— $9^{\circ}.8296 \times 0.6103$ , or the reduction for $0^{\text{h}} 36^{\text{m}} 37^{\text{s}}.16$ in Table II . . . . .	$— 0^{\text{m}} 6.00$
The required astronomical mean time . . . . .	May 14, $21^{\text{h}} 3^{\text{m}} 12.60$

Page IV contains *The Moon's Semidiameter* and *Equatorial Horizontal Parallax*, for each mean noon and midnight at Greenwich. Columns adjoining those of the horizontal parallax give the change of this quantity in one hour, by means of which it can be reduced to any other Greenwich mean time, in the same way as the sun's declination and the equation of time in the preceding examples. The sign plus or minus prefixed to the hourly differences, shows whether the horizontal parallax is increasing or decreasing.

The reduction of the moon's semidiameter may be readily found by multiplying the reduction of the horizontal parallax by 0.272. It may also be obtained from Table XI of BOWDITCH'S *Navigator*, or by simply computing the proportional part.

If, for example, the semidiameter of the moon is to be taken out for 1894, June 11, 10<sup>h</sup>, P. M., Greenwich mean time, we see that the difference of the semidiameters at noon and midnight of June 11 is 5''.8; then,

$$12^h : 10^h = 5''.8 : 4''.8,$$

which is the correction to be subtracted from the semidiameter at noon, because the semidiameter is decreasing. The moon's semidiameter then, for June 11, 10<sup>h</sup>, is 15° 40''.0 — 4''.8, or 15° 35''.2.

The moon's semidiameter and horizontal parallax are required for all observations of the moon. When great precision is needed, the hourly differences should be first interpolated for half the interval of Greenwich time from noon or midnight, and a correction applied to the horizontal parallax for the latitude of the place of observation.

The *Mean Time of the Moon's Upper Transit at Greenwich*, which is given on page IV to tenths of a minute, is also accompanied with a column of differences for one hour of longitude, by means of which, having the longitude converted into time, the local time of the moon's meridian passage at any other place, may be computed. The reduction may be taken by simple inspection from BOWDITCH'S Table XXVIII. The last column of this page contains the *Age* of the moon, or the time elapsed since the preceding new moon, to tenths of a day.

Pages V—XII contain *The Moon's Right Ascension*, and *Declination*, for each day and hour of Greenwich mean time. They are accompanied with columns of differences for one minute, which are also given at each hour. The Greenwich mean time, which is required for taking out these quantities, may be taken from a well-regulated chronometer, or obtained by applying the longitude converted into time, to the local mean time of the observer. The right ascension or declination is taken out for the day and hour of the Greenwich mean time; the *Diff. for 1 Minute* multiplied by the minutes and parts of a minute of the Greenwich time, and the product added to, or subtracted from the quantity, according as the quantity is increasing or decreasing.

Thus, suppose the moon's right ascension and declination are required for 1894, May 1, 10<sup>h</sup> 10<sup>m</sup> 30<sup>s</sup>, astronomical mean time at Greenwich:—

	Right Ascension.	Declination.
May 1, 10 <sup>h</sup>	<sup>h</sup> 23 42 11.62	S. 3° 26' 50''
Diff. 1°.9083 × 10.5	= + 20.04	15''.46 × 10.5 = — 2° 42.3
May 1, 10 <sup>h</sup> 10 <sup>m</sup> 30 <sup>s</sup>	23 42 31.66	S. 3° 24' 8.1

The differences interpolated for 5<sup>m</sup>.2 = 0<sup>h</sup>.09 are, for the right ascension 1°.9083, and for the declination 15''.46, which have been used for greater precision.

Page XII contains also the *Phases of the Moon* and the dates of the *Moon's Perigee and Apogee*, or least and greatest distances from the earth.

Pages XIII—XVIII contain the *Lunar Distances*, or the angular distances of the centre of the moon from the centre of the sun, and from the four larger planets and certain fixed stars, as they would appear to an observer at the centre of the earth. They are given for every third hour of Greenwich mean time, beginning at noon; the dates are therefore astronomical. All the distances that can be observed on the same day, are grouped together under that date; and the columns are read from left to right, across both pages of the same opening. The letter W. or E. is affixed to the name of the sun, planet or star, to indicate that it is on the west, or east side of the moon.

An observer on the earth's surface having measured a lunar distance, corrected it for errors of his instrument and for the semidiameter of the objects, and cleared it from the effects of refraction and parallax, finds the true or geocentric distance, that is, the distance as it would have appeared from the centre of the earth at the moment of observation. With this distance and the distances in the Ephemeris of the same bodies on the same day, the Greenwich mean time of the observation can be found.

To lessen the labor of computation, there is given in the Ephemeris, between every two successive distances, the logarithm of the seconds of time in which the distance changes 1"; or, as it is usually called, the *Proportional Logarithm of the Difference*. It is given for the middle instant of the two hours between which it is placed.

For computing the Greenwich time we have the following rule:—

*Find in the Almanac the two distances between which the true distance falls; take out the nearer of these, the hours of Greenwich time over it, and the P. L. of Diff. between them.*

*Find the difference between the true distance and the distance taken from the Almanac; and from the proportional logarithm of this difference, as found in the Navigator, subtract the P. L. of Diff. taken from the Almanac.*

*The result is the proportional logarithm of an interval of time to be added to the hours of Greenwich time, taken from the Almanac, when the earlier Almanac-distance is used; to be subtracted from the hours of Greenwich time, when the later Almanac-distance is used.*

Another method is, to add the common logarithm of the difference of the true and the Almanac-distances to the P. L. of Diff. of the Almanac; the sum will be the common logarithm of the correction to be applied to the hours of Greenwich time. The Table of *Logarithms of small Arcs in Space or Time*, given at the end of the volume for 1871, saves the operation of reducing degrees (or hours) and minutes to seconds, and the reverse.

As the P. L. of Diff. in the Ephemeris varies, the Greenwich time found by the methods just described may not be sufficiently exact. To correct it for such variation, or second difference, take the difference between the P. L. of Diff. used and the one which follows it in the Ephemeris, (or, more strictly, half the difference of the preceding and following ones). With this difference, and the first correction of the Greenwich time already found, enter Table I, appended to this volume, and take out the corresponding seconds, which are to be added to the approximate Greenwich time when the Prop. Logs. in the Ephemeris are decreasing; and subtracted when they are increasing.

Thus the Greenwich mean time of the observation can be obtained. If the observer has noted the time of observation by a chronometer, the difference of this chronometer-time and the Greenwich mean time will be the error of the chronometer on Greenwich time as found from the lunar distance. In this way lunar distances can be used as a check upon the chronometer. By a series of carefully observed lunar distances on both sides of the moon, the chronometer-error may generally be ascertained within 20 or 30 seconds.

If the observer has found the local mean time of observation from the observed altitude of one of the bodies, or by a watch regulated to that time by recent observations and corrected for change of longitude in the interval, the difference of this local time and the Greenwich time found from the lunar distance will be his longitude. A longitude derived by this method should always be considered as uncertain by 5' or more.

As an example of finding the Greenwich mean time from a lunar distance, suppose that in 1894, Oct. 10, the corrected distance of the moon's centre from that of Antares is  $80^{\circ} 50'$ :—

Corrected distance . . . . .	80° 51' 0"	P. L. 0.2966
Distance in Ephemeris Oct. 10, III <sup>b</sup> . . . . .	80° 42' 50"	P. L. 1.3432
Difference . . . . .	0° 8' 10"	P. L. 1.0466
Time from III <sup>b</sup> ( <i>after</i> ) . . . . .	+0° 16' 10"	
Corr. for 2d Diff., Table I . . . . .	+ 1	
Greenwich mean time Oct. 10 . . . . .	3° 16' 11"	

By a table of common logarithms, or a table of logarithms of small arcs, the reduction of the Greenwich time would be found thus:—

From Ephemeris . . . . .	. P.L. 0.2966
Diff. of distances, $8' 10'' = 490''$ . . . . .	. log 2.6902
Red. of Greenwich time, $970'' = 0^h 16^m 10^s$ . . . . .	. log 2.9868

The result is the same as by the previous method.

Pages 218—249 contain the geocentric ephemerides of the seven major planets. The positions are referred to the equator and true equinox of the date, and corrected for aberration; they are, therefore, apparent positions. All the data except meridian passage are given for the moment of Greenwich mean noon. The column *Meridian Passage* gives the hour, minute and tenth of that passage of the planet over the meridian of Greenwich which occurs next after the noon of the date.

The right ascension and declination of a planet are required whenever it has been observed for time, latitude or azimuth. The mode of reducing them to any instant of Greenwich mean time is the same as in the examples for the sun, previously given. The local mean time of passage across any other meridian can be found by dividing the daily differences by 24, and multiplying the quotient by the hours and fractions of the longitude of the place. The product is subtractive from the time of Greenwich passage when the place is east of Greenwich, and additive when west. The corrections can never exceed one-half the change for one day.

Pages 250—263 contain the heliocentric positions of the seven major planets, and the logarithms of their distances from the earth. The heliocentric longitude is reckoned, not from the true equinox, as in the preceding ephemerides, but from the mean equinox of the date. It is, therefore, necessary to apply nutation, if the longitude from the true equinox is required. The daily motion is given for the moment of Greenwich mean noon. The column *Reduction to Orbit* gives the correction to be applied to the heliocentric longitudes in order to obtain the longitude counted along the orbit of the planet. This longitude is equal to the distance of the node from the mean equinox, plus the distance of the planet from the node. The heliocentric latitude is counted from the moving plane of the ecliptic. The *Logarithm of Radius Vector* is the logarithm of the distance of the centre of the planet from that of the sun, at each Greenwich mean noon given in the first column. The two last columns give, in the same way, the logarithm of the true distance of the centre of the planet from that of the earth. The one column gives the quantity for the Greenwich noon indicated on the left hand side of the page, and the other for the noon which is midway between that date and the date next below it. In the case of Mercury, this intermediate date is mean noon of the day immediately following; in the case of Venus, Mars, Jupiter, and Saturn, it is mean noon of the second day following; and in the case of Uranus and Neptune, mean noon of the fourth day following.

Pages 264—271 contain the rectangular co-ordinates of the centre of the sun, referred to the centre of the earth as the origin, and to the true equator and equinox of each date as the circle and point of reference. Each co-ordinate is given first for Greenwich mean noon, and in the column following for mean midnight of the same day. The columns *Reduc. to Mean Eq'x of Jan. 0* give the corrections to be applied to the co-ordinates for noon in order to obtain the corresponding co-ordinates referred to the mean equator and the mean equinox of January 0.

Pages 272—275 give the longitude and latitude of the moon for every Greenwich mean noon and midnight. Both quantities are referred to the true ecliptic and equinox of the date.

Pages 276 and 277 contain the position of the moon's equator and the mean longitude of the moon, and a table for computing the libration of the moon. The epochs of greatest libration of the moon, together with the formulæ for finding the libration in longitude and latitude are given on page 419.

Page 278 contains, for each tenth Greenwich mean noon, the values of the principal elements arising from the motion of the equinox, and also the aberration and parallax of the sun. The column *Apparent Obliquity of the Ecliptic* (HANSEN) gives the true inclination of the earth's

equator to the ecliptic, without correction for the terms depending on the moon's longitude. The *Equation of Equinoxes* is really the astronomical nutation; that given *In Longitude* is the correction to be applied to the longitude of the body referred to the mean equinox, in order to obtain that longitude as referred to the true equinox. When the correction is positive, the true longitudes are greater than those referred to the mean equinox; while the contrary is true when the correction has the negative sign. The equation *In R. A.* is equal to that in longitude, multiplied by the cosine of the obliquity of the ecliptic.

The next column gives the *Precession of Equinoxes in Longitude*, from January 0 to each of the dates following. *The Sun's Aberration* is the quantity which is to be applied to the true longitude of the sun in order to obtain its apparent longitude. The correction being negative shows that the apparent longitude as affected by aberration is always less than the true longitude. *The Sun's Equatorial Horizontal Parallax*, given in the next column, is the angle subtended by the radius of the earth's equator, as seen from the centre of the sun.

**PART II—THE EPHEMERIS FOR THE MERIDIAN OF WASHINGTON.**

Page 280 contains the formulæ for reducing the positions of the fixed stars, using the notation of BESSEL, and the constants of PETERS and STRUVE. The formulæ by which the star-numbers are computed are also given.

Pages 281—284 contain the logarithms of the *Besselian Star-Numbers*,  $A$ ,  $B$ ,  $C$ ,  $D$ , for each Washington mean midnight. These numbers serve to reduce the mean place of a star at the beginning of the Besselian fictitious year to its apparent place at the dates for which the numbers are given. If used in accordance with the English and French notation, the pair of quantities  $A$  and  $B$  must be interchanged with the pair  $C$  and  $D$ ; that is,  $A$  must be interchanged with  $C$ , and  $B$  with  $D$ . In the first column along with the solar day is given, for certain dates, the sidereal hour and tenth of midnight. The sidereal time for which any set of quantities is given can be found by interpolation from these numbers.

The following is an example of the reduction of a star to apparent place by the Besselian star-numbers:—

**Computation of the apparent place of a *Hydra* for 1894, March 10, for the upper transit at Washington.**

(Star-Catalogue)	$\log a$	0.4699	$\log b$	7.8705	$\log c$	8.7164 n	$\log d$	8.6310
(Page 281)	$\log A$	9.1145	$\log B$	0.9776 n	$\log C$	1.2672 n	$\log D$	0.5249
(Star-Catalogue)	$\log a'$	1.1902 n	$\log b'$	9.8026 n	$\log c'$	9.7169	$\log d'$	9.0422
	$\log Aa$	9.5844	$\log Bb$	8.8481 n	$\log Ce$	9.9836	$\log Dd$	9.1559
	$\log Aa'$	0.3047 n	$\log Bb'$	0.7802	$\log Cc'$	0.9841 n	$\log Dd'$	9.5671

<i>Mean Place, 1894.0,</i>	$\alpha_0 =$	9 22 22.721	$\delta_0 =$	- 8 11 57.64"
	<i>A a =</i>	+ 0.384	<i>A a' =</i>	- 2.01
	<i>B b =</i>	- 0.070	<i>B b' =</i>	+ 6.03
	<i>C c =</i>	+ 0.963	<i>C c' =</i>	- 9.64
	<i>D d =</i>	+ 0.143	<i>D d' =</i>	+ 0.37
	<i>E =</i>	- 0.001	<i>E' =</i>	0.00
	$\tau \mu =$	0.000		

*Apparent Place, 1894, Mar. 10,*     $\alpha = \overline{9\ 22\ 24.140}$                    $\delta = -\overline{8\ 12\ 2.89}$

Pages 285—292 contain the *Independent Star-Numbers*, which can be used for the same purpose. The column  $\tau$  gives the fraction of the year from the beginning of the fictitious year to each date. These quantities are connected with those of BESSEL by the relations given on page 280, where are also found the formulæ and precepts for the application of both systems of numbers. In order to use the Besselian numbers, it is necessary to have the values of the star-constants,  $a$ ,  $b$ ,  $c$ ,  $d$ ,  $a'$ ,  $b'$ ,  $c'$ ,  $d'$ . The independent star-numbers are given in order that the apparent place of the star may be determined when it is not convenient to compute these numbers.

The following is an example of the reduction of a star to apparent place by the independent star-numbers:—

*Computation of the apparent place of α Hydræ for 1894, March 10, for the upper transit at Washington.*

$\alpha_o = 140^{\circ} 35.7$		$\delta_o = - 8^{\circ} 12'.0$		
$G = 285 22.0$		$G + \alpha_o = 65 57.7$		
$H = 280 17.2$		$H + \alpha_o = 60 52.9$		
$\log \frac{1}{r}$	= 8.8239	$\log \frac{1}{r}$	= 8.8239	$\alpha_o = 9^{\text{h}} 22^{\text{m}} 22.721^{\text{s}}$
$\log g$	= 0.9934	$\log h$	= 1.2742	$f = + 0.399$
$\sin(G + \alpha_o)$	= 9.9606	$\sin(H + \alpha_o)$	= 9.9413	$(g) = - 0.086$
$\tan \delta_o$	= 9.1586 n	$\sec \delta_o$	= 0.0045	$(h) = + 1.106$
$\log(g)$	= 8.9365 n	$\log(h)$	= 0.0439	$\tau \mu = 0.000$
				<i>Apparent R. A., α = 9 22 24.140</i>
$\log g$	= 0.9934	$\log h$	= 1.2742	$\delta_o = - 8^{\circ} 11' 57''.64$
$\cos(G + \alpha_o)$	= 9.6100	$\cos(H + \alpha_o)$	= 9.6672	$(g') = + 4.01$
$\log(g')$	0.6034	$\sin \delta_o$	= 9.1542 n	$(h') = - 1.31$
		$\log(h')$	= 0.1156 n	$(i) = - 7.94$
				$\tau \mu' = 0.00$
				<i>Apparent Dec., δ = - 8 12 2.88</i>
$\log i$	= 0.9046 n			
$\cos \delta_o$	= 9.9955			
$\log(i)$	= 0.9001 n			

Pages 293—301 contain the mean places of three hundred and eighty-three stars, for the beginning of the fictitious year 1894, or the moment when the sun's mean longitude is  $280^{\circ}$ .

The annual variations are to be considered as the differential coefficients of each co-ordinate with respect to the time at the beginning of the year.

In order that the list of mean places of stars may serve the purpose of a working-catalogue for the convenient use of astronomers, the position of each of the northern circumpolar stars is given in duplicate, one position being for the upper and the other for the lower culmination. The positions for the lower culmination are marked S. P. In this case, the right ascensions are the sidereal times at which the star crosses the lower meridian; and, in order to have the expressions for the co-ordinates congruous in all cases, the declinations are counted from the equator through the north pole, and therefore exceed  $90^{\circ}$ . The time of observation and the setting of the circle, in order to find a star on the meridian, are then obtained uniformly for all the stars.

Beginning with the volume of 1882, the number of stars has been greatly increased, in order to make the list more useful to field-astronomers. In order to show at a glance these additional stars, they are indicated in the list by an asterisk.

Pages 302—313 contain the apparent positions of the four north polar stars, α, δ and λ Ursæ Minoris, and 51 Cephei, for every upper transit at Washington. They include the terms depending on the moon's longitude. The mean solar time of transit is given in the column *Mean Solar Date*, in order that each transit above and below the pole may be readily identified. Suppose, for example, that the transit of Polaris below the pole on January 26th is to be found, and we wish to know whether it precedes or follows the upper transit of the same date. On page 302, we find that the upper transit occurs January 26.2; the lower transit, therefore, occurs January 26.7. But, the lower transit following that of July 1st (page 308), does not take place until July 2.3. Hence, the lower transit of July 1st precedes the upper one of the same date. A transit occurring very nearly at noon may also be identified without a computation to ascertain the actual mean date, by simply noting the tenth of a day in the column of *Mean Solar Date*.

Pages 314—364 contain, for every tenth upper transit at Washington, the apparent places of those stars of the preceding list which are not marked with an asterisk. The mean solar date in each left hand column gives the day and tenth of the transit; so that each intermediate transit

may be readily identified. Along with each co-ordinate is given, in small type, the change for ten days. This quantity is to be regarded as the differential coefficient corresponding to the dates for which the star-places are given.

Pages 365—376 contain the apparent right ascensions of all stars marked with an asterisk in the list of mean places. The apparent right ascension of each star is given only for that part of the year when it may readily be observed on the meridian. In the case of circumpolar stars, the right ascensions for lower, as well as upper, transit are given.

Pages 377—384 contain the apparent right ascension, declination, and semidiameter of the sun, and the sidereal time, all for Washington mean noon. Adjoining columns give the seconds of right ascension and of declination for apparent noon, that is, for the moment of transit of the sun's centre over the meridian of Washington. The hours and minutes of right ascension, and the degrees and minutes of declination are the same for both mean and apparent noon. In case they would have differed, the minute which would have been numerically larger is diminished by one, and the seconds increased by sixty, so that there is always a correspondence between the two numbers. The hourly motions in right ascension and declination are given for the moment of mean noon, but may be regarded as having the same values for apparent noon.

The *Equation of Time for Apparent Noon* is the correction to be applied to apparent time in order to obtain mean time. It is, therefore, mean time minus apparent time. Each number as given is the mean time of transit of the sun's centre over the meridian of Washington, counted from the nearest noon. The use of all the quantities is substantially the same as in the *Ephemeris for the Meridian of Greenwich*.

Pages 385—392 contain the right ascension, declination, semidiameter, and parallax of the moon, at the moment of transit over the meridian of Washington. The mean time given in the second column is that of transit of the moon's centre over this meridian. The differences for one hour of longitude are the amounts by which the local mean times of transit over a meridian one hour west of Washington exceed those given in the column *Mean Time of Transit*, supposing the rate of change to be uniform and equal to what it is at the moment of transit over the meridian of Washington. The next four columns need no especial explanation, except that the differences for one hour of longitude are computed as if the motion of the moon in right ascension were uniform. By means of them, the position of the moon can be computed with astronomical accuracy at the moment of transit over any meridian not exceeding one hour in longitude from that of Washington, by taking account of second differences. With greater longitudes of the place, the accuracy of the result obtained in this way will diminish. The columns of sidereal time of semidiameter passing meridian, etc., do not seem to need any explanation, except that they all refer to the moment of transit. The column *Bright Limbs* is given to indicate to the observer which limbs are illuminated. When two opposite limbs are both so nearly full that they can be well observed, both are indicated; and the one which is deficient is printed in smaller type. When the illumination is so nearly equal that no choice can be made between them, both are printed in large type.

Pages 393—410 contain the geocentric apparent right ascensions and declinations of the seven major planets, and their semidiameters and horizontal parallaxes, for the moments of all those transits over the meridian of Washington which can be observed.

### PART III—PHENOMENA.

This portion of *The American Ephemeris and Nautical Almanac* gives the principal astronomical phenomena of the year, reduced to Washington mean time, except in the case of the eclipses and the data for the rings of Saturn, which are given in Greenwich mean time.

Pages 412—418 inclusive contain the elements necessary for computing the eclipses of the sun and a transit of Mercury which occur during the year.

The eclipse-elements are given for the moment of conjunction of the sun and moon in right ascension. The subsequent tables and results are not, however, computed from these

elements unchanged; but from the accurate positions of the two bodies as interpolated for each hour of the eclipse. The principal circumstances of each eclipse are as follow:—

On the line "Eclipse begins" is given the Greenwich mean time at which the earth first touches the moon's penumbra, and the longitude and latitude of the point of touching.

The "Central eclipse begins" when the axis of the moon's shadow first touches the earth, and the longitude and latitude of the point of touching follow.

"Central eclipse at noon" indicates the moment when the axis of the shadow is coincident with the plane of the meridian at the point of its intersection with the earth's surface. To the observer at this point, the eclipse will be central at the moment of apparent noon.

"Central eclipse ends" and "Eclipse ends" have the converse meaning of the beginning.

*Maps of the Eclipses.*—The regions in which each eclipse is visible, are shown upon the maps given in connection with them. From these maps may also be derived the approximate determination of the times of beginning and ending, and of the magnitude of the eclipses at any place. The dotted curves show the outlines of the shadow for each hour of Greenwich mean time and therefore pass through all the places where the eclipse begins or ends at that hour. To find at what hour the eclipse begins at any place, we determine by inspection between what pair of these curved lines the place is situated. The eclipse will then begin between these two hours of Greenwich mean time: the fraction of the hour may be determined by dividing the hour proportionally to the space which it represents on the map. This division may be a little more exact by allowing for the changes in this space as indicated by their varying width. The Greenwich mean time thus found must be reduced to local mean time by applying the longitude.

As an example, suppose we wish to find the time at which the eclipse of 1894, April 5, begins and ends at Chicacole.

For the beginning we compare the distance of the place from the curves of 14<sup>h</sup> and 15<sup>h</sup> and we find it to correspond to about 20 minutes from the former, therefore the time of beginning is approximately 13<sup>h</sup> 40<sup>m</sup>; for the end we compare the distance of the place from the curves of 16<sup>h</sup> and 17<sup>h</sup> and find it to be about 18 minutes from the former, therefore the approximate time of end is 16<sup>h</sup> 18<sup>m</sup>, both of which are probably correct to within 2 or 3 minutes. Changing to local mean time the result will be:—

	Beginning.	Ending.
	<i>d h m</i>	<i>h m</i>
Greenwich mean time . . . . .	April 5 13 40	16 18
Longitude East . . . . .	5 36	5 36
Local mean time . . . . .	April 5 19 16	April 5 21 54

In the case of total and annular eclipses, a rough estimate of the magnitude of the eclipse may be obtained from the position of the place relatively to the central line and to the limit. On the central line, the eclipse is annular or total, while on the limit, the limb of the moon only grazes that of the sun.

*More Accurate Computations.*—A more accurate determination of the phases as visible at any point of the earth's surface may be obtained from the Besselian elements which are given for every ten minutes of Greenwich mean time. Their geometric signification is as follows:—

Let us imagine a plane passing through the centre of the earth, perpendicular to the right line joining the centres of the sun and moon. This latter line is the axis of the moon's shadow, and the plane is called the *fundamental plane*. We take the intersection of this plane with that of the earth's equator as the axis of *X*, and the centre of the earth as the origin of co-ordinates. The axis of *Y* is perpendicular to that of *X*, and directed toward the north; *x* and *y* are then the co-ordinates of the point in which the axis of the shadow intersects the fundamental plane. The angle *d*, of which the sine and cosine are both given, is the declination of that point of the celestial sphere toward which the axis of the shadow is directed; this direction being that from the earth toward the moon and sun. The angle *μ* is the Greenwich hour-angle of this same point of the celestial sphere.

The quantities  $l$  and  $l'$  are the radii of the shadow-cones upon the fundamental plane,  $l$  corresponding to the penumbra, and  $l'$  to the umbra, or annulus. The notation is that of CHAUVENET's *Spherical and Practical Astronomy*, in which  $l'$  is regarded as positive for an annular, and negative for a total eclipse.

The angles  $f$  and  $f'$ , the tangents of which are given, are the angles which the elements of the respective shadow-cones make with the axis of the shadow; or, they are the semi-angles of the two cones.

At the bottom of the table are given the logarithms of the change of  $x$ ,  $y$  and  $\mu$ , in one minute, in order to facilitate the interpolation to any required moment.

The method of computing the eclipse from the given elements is as follows: It is premised that the moments of beginning and ending are those at which the distance of the observer from the axis of the shadow or penumbra is equal to the radius of the latter at the point of observation. To find such distance and radius we compute—

(1) The co-ordinates,  $\xi$ ,  $\eta$  and  $\zeta$ , of the observer, at some assumed moment of Greenwich mean time, as near as practicable to the true time of the required phase, together with their variations for one minute.

(2) The co-ordinates  $x$  and  $y$  of the axis of the shadow at the same moment, which, with their variations for one minute, are taken from the tables of elements.

(3) Hence, the position and motion of the observer relative to the axis of the shadow.

(4) The radius of the penumbra or umbra at a distance from the fundamental plane equal to that of the observer.

(5) Then, assuming the motions to be uniform, we determine the time required for the observer to be brought to a distance from the axis of the shadow equal to this radius.

The formulæ and directions for the several steps in the computation are as follow:—

(1) Find the geocentric co-ordinates of the station referred to the earth's equator, which are represented by  $\rho \cos \varphi'$  and  $\rho \sin \varphi'$ ,  $\rho$  being the distance from the centre of the earth, and  $\varphi'$  the geocentric latitude. These may be obtained from geodetic tables, or may be computed from the following table by the formulæ—

$$\rho \cos \varphi' = F \cos \varphi$$

$$\rho \sin \varphi' = \frac{\sin \varphi}{G}$$

$\varphi$  being, as usual, the geographic latitude.

Table for Computing the Geocentric Co-ordinates of a Place.

$\varphi$	Log $F$ .	Log $G$ .
0°	0.00000	0.00302

85	0.00150	4 0.00152 3
90	0.00151	1 0.00151 1

For the assumed Greenwich mean time of computation, take from the table of elements the values of  $\sin d$ ,  $\cos d$ , and  $\mu$ . Put:

$\lambda$ , the longitude west from Greenwich. The co-ordinates of the observer will then be:—

$$\xi = \rho \cos \varphi' \sin (\mu - \lambda)$$

$$\eta = \rho \sin \varphi' \cos d - \rho \cos \varphi' \sin d \cos (\mu - \lambda)$$

$$\zeta = \rho \sin \varphi' \sin d + \rho \cos \varphi' \cos d \cos (\mu - \lambda)$$

and their variations in one minute of mean time will be:—

$$\xi' = [7.63992] \rho \cos \varphi' \cos (\mu - \lambda)$$

$$\eta' = [7.63992] \rho \cos \varphi' \sin d \sin (\mu - \lambda) = [7.63992] \xi \sin d$$

$\zeta'$  is not wanted.

(2) The co-ordinates  $x$  and  $y$  of the axis of the shadow are taken from the tables of elements for the same assumed moment of Greenwich mean time, together with their variations for one minute, which are equal to one-tenth of the differences of two consecutive numbers. The variations for one minute we represent by  $x'$  and  $y'$ . Their logarithms are given at the foot of the tables.

(3) The distance  $m$  and position-angle  $M$  of the axis of the shadow relative to the observer, and the relative motions,  $n$  and  $N$ , are computed by the formulæ:—

$$m \sin M = x - \xi$$

$$m \cos M = y - \eta$$

$$n \sin N = x' - \xi'$$

$$n \cos N = y' - \eta'$$

(4) The radius  $L$  of the shadow or penumbra at the distance  $\zeta$  from the fundamental plane is computed by the formula

$$L = l - \zeta \tan f$$

$l$  and  $f$  being found in the table of elements, and  $\zeta$  computed in (1).

(5) If the time chosen for computation is exactly that of the beginning or end of the eclipse, we shall have—

$$m = L$$

But, as this condition can scarcely ever be fulfilled on a first trial, a correction  $\tau$  to the assumed time is computed thus: Find the angle  $\phi$  from the equation,

$$\sin \phi = \frac{m \sin (M - N)}{L}$$

There will be two values to this angle, of which one will be in the first and the other in the second quadrant when  $\sin \phi$  is positive, and one in the third and the other in the fourth when  $\sin \phi$  is negative. But, simplicity will be gained by taking only that value of  $\phi$  for which  $\cos \phi$  is positive. This value lies between the limits  $+90^\circ$  and  $-90^\circ$ . The correction  $\tau$  to the assumed time will be found in minutes, from—

$$\text{For beginning: } \tau = - \frac{m \cos (M - N)}{n} - \frac{L \cos \phi}{n}$$

$$\text{For ending: } \tau = - \frac{m \cos (M - N)}{n} + \frac{L \cos \phi}{n}$$

One such pair of values of  $\tau$  cannot, however, give the times of both beginning and ending with accuracy. To attain accuracy we must, in commencing the computation, assume two times, one near that of beginning, and another near that of ending. These approximate times may be derived from the chart of the eclipse. The computation for the first assumed time will give a small value of  $\tau$  which, applied to the assumed time, will give a nearly correct time for the beginning of the eclipse, and a large value which, added to the assumed time, will give an inaccurate time of ending. The computation for the second assumed time will give a small and nearly correct value of  $\tau$ , to be applied to the assumed time for the end, and a large negative and inaccurate one to be subtracted for the beginning. We shall thus deduce two times of each phase only one of which is to be considered approximately correct.

The more accurate times of beginning and ending may now be taken in place of the first assumed ones, and the computation may be repeated from the beginning, leading to a pair of values of  $\tau$ , which should be very small and accurate. Such a repetition of the computation will in general be advisable, to guard against accidental numerical errors. The following theorem will, however, enable us to obtain a second approximation to the true times of each phase without repeating the computation.

**THEOREM.**—*The error of each result is approximately proportional to the square of the correction  $\tau$ , multiplied by the sine of the sun's hour-angle, ( $\mu - \lambda$ ), for the middle of the interval between the time of computation and that of the phase.*

To apply this theorem we find the two values of  $\tau^2 \sin (\mu - \lambda)$  corresponding to the required phase. We then find the ratio of these quantities—which will commonly be a large number, and divide the difference of the results by this ratio. The quotient will be a correction to be applied to the more accurate result in such a way as to make it deviate yet more from the less accurate one. This correction should be positive in the local forenoon, and negative in the afternoon, and its value should never materially exceed  $0^m.001 \tau^2$ .

Unless the times chosen for computation are unusually in error, say ten minutes or more, the corrected results thus obtained will be theoretically correct within less than a second. But to guard against numerical errors it is better, after making this final correction, to repeat the computations so far as to obtain new values of  $m$  and  $L$  for the corrected times. If these two quantities agree within a unit of the fourth place of decimals, the times employed are generally correct within a second of time. If they differ too widely, further corrections and computations may be made by the computer according to his own judgment.

It may be remarked that the uncertainty of the ephemerides is such that a prediction may be several seconds in error from this unavoidable cause alone.

**Position-angle of Point of Contact.**—The position-angle  $P$ , of the point of contact, reckoned from the north point of the sun's limb toward the east, is found by the formula

$$\text{For beginning: } P = N - \phi \pm 180^\circ$$

$$\text{For end: } P = N + \phi$$

it being assumed that, in each case, the value of  $\phi$  is taken between the limits  $\pm 90^\circ$ .

Computation of the Solar Eclipse of 1894, April 5, for Vizagapatam, India, whose position is—

$$\text{Latitude, } \varphi = + 17^\circ 41' 34''$$

$$\text{Longitude, } \lambda = - 83^\circ 17' 42''$$

Constants for the given place:—

$$\rho \sin \varphi' = 9.47999$$

$$\rho \cos \varphi' = 9.97910$$

From the Eclipse Charts we find the approximate times of the phases to be—

*Elements of Occultations.*—Pages 420—449 give the elements for the prediction of the times of occultation of stars and planets by the moon. In the columns referring to the star, those headed *Redns from 1894.0* give the quantities necessary to reduce the mean place of the star at the beginning of 1894 to its apparent place at the time of occultation. These reductions are sufficiently accurate to be definitive.

The quantities in the following five columns are all given for the moment of geocentric conjunction of the star and moon in right ascension. Let there be a line passing from the star through the centre of the moon, and let a plane perpendicular to this line pass through the centre of the earth: this plane will be the fundamental plane for the occultation. The system of co-ordinates is similar to that already described for eclipses. The cone circumscribing the moon and star may be regarded as a cylinder having everywhere the same diameter as the moon. This cylinder will intercept the fundamental plane in a circle of which the linear diameter will be the same as that of the moon.

The *Washington Mean Time* is the moment at which the two bodies are in geocentric conjunction in right ascension. At this moment the co-ordinate  $x$  of the axis of the cylinder on the fundamental plane has the value zero. The column *Hour-Angle H* gives the common geocentric hour-angle of the moon and star at the same moment, counted from the meridian of Washington—positive toward the west and negative toward the east. Column Y gives the co-ordinate  $y$  of the axis of the cylinder upon the fundamental plane at the same moment. Columns  $x'$  and  $y'$  give the hourly variation of  $x$  and  $y$ . The linear unit in these columns is the earth's equatorial radius. The limiting parallels, north and south, show the extreme limits of latitude within which the occultation will be visible.

By the aid of these elements, the Washington mean time of immersion and emersion of a star behind the limb of the moon may be computed for any part of the earth by a method nearly the same as that already explained for computing eclipses, only more simple.

We shall first show how to compute an isolated occultation for a particular place, assuming it to be visible at that place, and then show how all the occultations which will be visible at a place may be selected and computed by a more rapid process.

(1) The geocentric co-ordinates of the place,  $\rho \sin \varphi'$  and  $\rho \cos \varphi'$ , are to be computed with three or four places of decimals by the formulæ,

$$\begin{aligned}\rho \sin \varphi' &= \frac{\sin \varphi}{G} \\ \rho \cos \varphi' &= F \cos \varphi\end{aligned}$$

already given in connection with the eclipses.

As in the case of eclipses, it is necessary to have an approximate time of the phenomenon, corresponding to that obtained from the charts of the eclipses. The quantity  $H$  being the Washington west hour-angle of the two bodies at the moment of geocentric conjunction,  $H - \lambda$  will be the local hour-angle of the star at this same moment. Let us call this angle  $h_o$ , putting

$$h_o = H - \lambda$$

where  $\lambda$  is the longitude west of Washington.

The next step will then be to find the approximate moment of apparent conjunction in right ascension as seen from the place. An approximate correction to reduce the time and hour-angle for geocentric conjunction to those for apparent conjunction may be taken from Mr. DOWNES's table, on pages 452—453. This correction will have the same sign as  $h_o$ .

When this table is not available, the correction may be computed thus: Compute the quantities  $\xi_o$ ,  $\xi'$  and  $\tau$  from the formulæ,

$$\begin{aligned}\xi_o &= \rho \cos \varphi' \sin h_o \\ \xi' &= [9.4192] \cos (h_o + \frac{1}{2} h_o) \\ \tau &= \frac{\xi_o}{x' - \xi'}\end{aligned}$$

$\tau$  will then be the approximate interval between the times of geocentric and local conjunction.

By applying it to the Washington mean time of the former, as given with the elements, we shall have the Washington mean time of the latter within a few minutes.

The average duration of an occultation is about an hour. Thence, by adding  $0^{\text{h}}.5$  to and subtracting it from the mean time of apparent conjunction, we shall have approximate times of the phases of immersion and emersion for farther computation. Let us then put,

$$\tau_1 = \tau - 0^{\text{h}}.5$$

$$\tau_2 = \tau + 0^{\text{h}}.5$$

$T$ , the Washington mean time of geocentric conjunction in R. A.

$d$ , the declination of the star.

(2) Compute for the moments  $T + \tau_1$  and  $T + \tau_2$  the following quantities, in which we write  $\tau$  for each of the quantities  $\tau_1$  and  $\tau_2$ . The latter, when used as angles, are to be changed to arc by multiplying by 15, and the minutes are to be further increased by one-sixth the number of degrees in order to reduce to the sidereal hour-angle.

$$\xi = \rho \cos \varphi' \sin (h_0 + \tau)$$

$$\eta = \rho \sin \varphi' \cos d - \rho \cos \varphi' \sin d \cos (h_0 + \tau)$$

$$\xi' = [9.4192] \rho \cos \varphi' \cos (h_0 + \tau)$$

$$\eta' = [9.4192] \rho \cos \varphi' \sin d \sin (h_0 + \tau) = [9.4192] \xi \sin d$$

$$x = x' \tau$$

$$y = Y + y' \tau$$

Compute  $m$ ,  $M$ ,  $n$  and  $N$  from the equations

$$m \sin M = x - \xi$$

$$m \cos M = y - \eta$$

$$n \sin N = x' - \xi'$$

$$n \cos N = y' - \eta'$$

$$n' = \frac{n}{60} = [8.2218] n$$

$$\sin \psi = [0.5650] m \sin (M - N)$$

Then,  $t_1$  and  $t_2$  from the equations

$$t_1 = -\frac{m}{n'} \cos (M - N) - \frac{[9.4350]}{n'} \cos \psi \quad (\text{Beginning.})$$

$$t_2 = -\frac{m}{n'} \cos (M - N) + \frac{[9.4350]}{n'} \cos \psi \quad (\text{End.})$$

The quantities  $t_1$  and  $t_2$  will then be the corrections in minutes to be applied to the respective times  $T + \tau_1$  and  $T + \tau_2$  to obtain the Washington mean times of the phases.

As in the case of eclipses, the small value of  $t_1$  will give an accurate result for one phase, and the large value an inaccurate result for the other. Both accurate results may then be corrected by comparison with the inaccurate one, in the way described for eclipses, and a result obtained which will probably be correct within a fraction of a minute of time.

As a check upon the result, it will be advisable to compute  $\xi$ ,  $\eta$ ,  $x$  and  $y$  for the moments finally obtained. If the times are correct these quantities will fulfil the condition,

$$\sqrt{(x - \xi)^2 + (y - \eta)^2} = 0.2723$$

If  $\log m \sin (M - N) = 9.4350$  nearly, a recalculation will generally be necessary to determine whether, numerically,  $\sin \psi < 1$ , or  $\sin \psi > 1$ . In the latter case, the impossible value of  $\sin \psi$  indicates that an occultation at the given place is impossible, unless the computed distance from the moon's limb is within the errors of the ephemerides of the moon and star.

In such cases of near approach to the moon's limb, we may take  $\psi = 90^\circ$ , or  $270^\circ$ , according as  $\sin (M - N)$  is positive or negative; and for finding the time of nearest approach,

$$t = -\frac{m \cos (M - N)}{n'}$$

Putting  $\pi$  for the moon's horizontal parallax, the distance from the moon's limb will be,

$$\pi [m \sin(M - N) - 0.2723]$$

disregarding the sign of  $\sin(M - N)$ ; or, allowing for the augmentation of the semidiameter,

$$\pi [m \sin(M - N) - 0.2723] [1 + z \sin \pi]$$

where

$$z = \rho \cos \varphi' \cos d \cos(h_0 + \tau) + \rho \sin \varphi' \sin d$$

The position-angle  $P$ , of the line from the moon's centre to the star at the times of contact, reckoned from the north point toward the east, is given by the formulæ:—

$$P = N - \psi \quad \text{for immersion,}$$

$$P = N + \psi \pm 180^\circ \quad \text{for emersion,}$$

it being supposed that the value of  $\psi$ , in each case, is taken between the limits  $\pm 90^\circ$ .

To find the angle from the vertex, we compute the angle  $C$  from the formula,

$$\tan C = \frac{\xi + t \xi'}{\eta + t \eta'}$$

in which the value of  $t$  corresponding to the phase is to be used. Then

$$V = P - C$$

is the angle from the vertex, also reckoned from the north toward the east.

As an example of an isolated occultation, we will compute that of  $\beta$  Virginis, on March 20, 1894, for Hanover, whose position is

$$\varphi = + 43^\circ 42' 15''$$

$$\lambda = - 0^h 19^m 4.^s13$$

Constants for the given place,

$$\rho \sin \varphi' = 9.83722$$

$$\rho \cos \varphi' = 9.85978$$

From the elements on page 426, we have

$$H = - 0^h 31.^m7$$

$$h_0 = H - \lambda = - 0^h 12.631$$

From Downes's Table, pages 452 and 453, or from the formulæ on page 512, we find the correction to the Washington mean time of geocentric conjunction to be about  $-5^m$ , therefore the Washington mean time of apparent conjunction at the given place is March 20<sup>d</sup> 11<sup>h</sup> 13<sup>m</sup>.7; adding and subtracting  $30^m$ , we shall have the approximate Washington mean times of immersion and emersion to be used in the computation, thus:

$$\begin{aligned} \tau_1 &= - 0^h 35^m \\ \tau_2 &= + 0^h 25^m \end{aligned}$$

$$\begin{aligned} T + \tau_1 &= \text{March } 20^d 10^h 43.7^m \\ T + \tau_2 &= \quad \quad \quad 20^d 11^h 43.7^m \end{aligned}$$

from the north point of the moon's limb towards the east for direct image.

*Prediction of Many Occultations for a Given Place.*—When it is desired to predict all the occultations which will be visible at some one place, tables may be constructed and applied in such a way as to greatly diminish the labor of computation. In using such tables, the most convenient course will be to find for each occultation the hour-angle of the star at the moment of apparent conjunction in right ascension, as seen from the place of observation. The table of elements, pages 420—449, gives  $H$ , the Washington hour-angle at the moment of geocentric conjunction. The corresponding geocentric hour-angle at the place will be

$$h_o = H - \lambda \quad (\lambda = \text{west longitude from Washington}).$$

The moment of apparent conjunction, as seen from the station, will be given by the condition  $\xi = x$ ; or, using the values of  $\xi$  and  $x$ ,

$$\rho \cos \varphi' \sin h = x' \tau$$

$h$  being the west hour-angle of the star at the moment in question, and  $\tau$  the interval, in hours of mean time, which has elapsed since geocentric conjunction. We shall therefore have,

$$h = h_o + \tau$$

for the hour-angle at the end of the interval  $\tau$  after geocentric conjunction. In strictness,  $\tau$  should here be multiplied by the factor  $1 + \frac{1}{365.25}$ , because the star moves a little more than  $15^\circ$  in an hour of mean time; but the error arising from the neglect of the factor is too small to be important, as it will affect the predicted time of conjunction by less than 10 seconds. The equation for finding  $\tau$  is therefore,

$$\rho \cos \varphi' \sin (h_0 + \tau) = x' \tau$$

The quantities  $h_0$  and  $x'$  being derived immediately from the data of the Ephemeris, the quantity  $\tau$  is readily obtained by successive approximation, and may be tabulated as a function of  $h_0$  and  $x'$ . The computation of  $\tau$  is effected as follows. We have

$$\sin (h_0 + \tau) = \sin h_0 + 2 \sin \frac{1}{2} \tau \cos (h_0 + \frac{1}{2} \tau) \quad (1)$$

The value of  $\tau$  in arc being seldom more than  $24^\circ$  we may put  $\tau$  itself for  $2 \sin \frac{1}{2} \tau$ . The equation will then become

$$\rho \cos \varphi' \sin h_0 + \tau \rho \cos \varphi' \cos (h_0 + \frac{1}{2} \tau) = x' \tau$$

from which we find

$$\tau = \frac{\rho \cos \varphi' \sin h_0}{x' - \rho \cos \varphi' \cos (h_0 + \frac{1}{2} \tau)} \quad (2)$$

To tabulate  $\tau$ , we must first have a table of the quantities

$$\begin{aligned} \xi &= \rho \cos \varphi' \sin h \\ \xi' &= [9.41916] \rho \cos \varphi' \cos h \end{aligned} \quad (3)$$

which table may be formed for every 10 minutes (in time) of  $h$ . If we then put  $\xi_0$  for the value of  $\xi$  corresponding to  $h = h_0$  and  $\xi'_1$  for the value of  $\xi'$  corresponding to  $h = h_0 + \frac{1}{2} \tau$ , we shall have

$$\tau = \frac{\xi_0}{x' - \xi'_1} \quad (4)$$

Since we must know the value of  $\tau$ , approximately, before we can take  $\xi'_1$  from the table, this equation can be solved only by successive approximations. The approximations converge so rapidly as to offer no difficulty. It will be best to begin by comparing values of  $\tau$  for the two extremes of  $x'$ , namely,  $x' = 0.48$  and  $x' = 0.60$ , because the approximate values of  $\tau$  can then be interpolated for all the intermediate values of  $x'$ . For the first approximation may be taken—

$$\begin{aligned} \frac{1}{2} \tau &= 50^m \sin \frac{4}{3} h_0 \quad (\text{for } x' = 0.48) \\ \frac{1}{2} \tau &= 40^m \sin \frac{4}{3} h_0 \quad (\text{for } x' = 0.60) \end{aligned} \quad (5)$$

or, the approximate values of  $\tau$  may be taken from Mr. Downes's table, pages 452—453. It will be best to make the computation for every  $30^m$  of  $h_0$ , and to find the intermediate values of  $\tau$  for every  $10^m$  by interpolation. Then for each  $30^m$  of  $h_0$  we take  $\xi'$  from a table with the argument  $h_0 + \frac{1}{2} \tau$ , and  $\log \xi$  with the argument  $h_0$ , and thence compute  $\tau$  by (4). If the value of  $\tau$  thus arrived at differs more than  $3^m$  from that employed in taking out  $\xi'$ , a new value may be used to correct  $\xi'$ , and the computation may be repeated. The values corresponding to  $x' = 0.51$ ,  $x' = 0.54$ , and  $x' = 0.57$ , can then be computed with the single interpolation of approximate values of  $\tau$ , and afterward the table can be extended by interpolation to every 0.01 of  $x'$  between  $x' = 0.48$  and  $x' = 0.60$ . It will be best to compute  $\tau$  in the first place to every 0.001 of an hour, and to drop the last figure in forming the definitive table. The table thus formed will be called *Table I*.

The values of  $\eta$  and  $\eta'$  may then be tabulated for every degree of the star's declination, and every  $10^m$  of  $h$ . It is a mere question of convenience whether to compute the table for negative values of  $d$ , since by putting

$$\begin{aligned}\eta_1 &= \rho \sin \varphi' \cos d \\ \eta_2 &= -\rho \cos \varphi' \sin d \cos h\end{aligned}$$

$\eta_1$  may be given in a table of single-entry; and taking  $\eta_2$  from the table of double-entry for a positive  $d$ , we shall have

$$\eta = \eta_1 \pm \eta_2$$

the lower sign being used for a negative  $d$ . But the extension of the table for  $\eta$  to negative values of  $d$  is so readily made that it will probably be found better to do it, so as to save taking out  $\eta_1$  and  $\eta_2$  separately.

This table for  $\eta$  will be called *Table II*, and the corresponding one for  $\eta'$  with the same arguments *Table III*. The precepts for using the tables will then be as follow:—

From Table I with the arguments  $x'$  and  $H - \lambda = h_o$  take out the value of  $\tau$ . It will be sufficient to use the nearest  $0.01$  of  $x'$ .  $\tau$  will be of the same sign as  $h_o$ . Then, enter Table II with the arguments  $d$  (the star's declination) and  $h = h_o + \tau$ , and take out the value of  $\eta$ . Form the quantities  $y = Y + y' \tau$ , and  $y - \eta$ . If the latter quantity lies between the limits  $\pm 0.28$ , it is almost certain that there will be an occultation. If it falls without the limits  $\pm 0.33$ , it is almost certain that there will not be an occultation. Between the years 1881 and 1894 these last limits may be reduced to  $\pm 0.32$ , and cases near this limit may be rejected if  $y$  is small. A convenient rule to adopt will be—

$y' < 0.10,$	$= \pm 0.29$
$0.10 < y' < 0.15,$	$= \pm 0.30$
$0.15 < y' < 0.20,$	$= \pm 0.31$
$0.20 < y'$	$= \pm 0.33 \text{ or } \pm 0.32$

Here, only the absolute value of  $y'$  is to be considered, without respect to its algebraic sign.

If  $y - \eta$  falls between the limits thus indicated, take the values of  $\xi'$  and  $\eta'$  from the appropriate tables and compute  $v$ ,  $Q$  and  $\Delta$  from the equations

$$\begin{aligned}v \sin Q &= y' - \eta' \\ v \cos Q &= x' - \xi' \\ \Delta &= (y - \eta) \cos Q\end{aligned}$$

If  $\Delta > 0.2723$  or  $\log \Delta > 9.4350$  there will be no occultation, though the moon may graze the star when  $\Delta = 0.2723$  is very small. If  $\Delta < 0.2723$ , compute

$$\begin{aligned}\tau_1 &= -\frac{y - \eta}{v} \sin Q & \cos P &= \frac{\Delta}{0.2723} & (P < 180^\circ) \\ \tau_2 &= \frac{0.2723 \sin P}{v}\end{aligned}$$

We shall then have—

Local mean time of immersion,  $T - \lambda + \tau + \tau_1 - \tau_2$

Local mean time of emersion,  $T - \lambda + \tau + \tau_1 + \tau_2$

Position-angle from north toward east at immersion,  $180^\circ - Q - P$

Position-angle from north toward east at emersion,  $180^\circ - Q + P$

In predicting the occultations for a given place, the first operation will be to go over the list of occultations in the Ephemeris, and select those which may be visible. The conditions of possible visibility are:—

1. The limiting parallels in the last columns must include the latitude of the place.

2. The quantity  $H - \lambda$ , taken without regard to sign, must be less than the semi-diurnal arc of the star by at least one hour. On very rare occasions an emersion might be seen in the east horizon, or an immersion in the west, when this difference is a few minutes less than an hour.

3. The sun must not be much more than an hour above the horizon at the local mean time  $T - \lambda$ , unless the star is bright enough to be seen in the day time.

The most convenient course will be to write the value of  $-\lambda$  on the bottom of a sheet of paper, and passing through the list of occultations, pause over each one for which condition (1) is fulfilled, and examine whether conditions (2) and (3) are fulfilled. If either fails, the computer passes on. Very often it will require some examination to find whether  $H - \lambda$  or  $T - \lambda$  falls within the limits; in these cases, the computer may mark the occultation for trial and leave the decision for the subsequent operations. The whole list can be gone over in less than a day, and it will probably be found that about one-tenth of the occultations are marked for trial.

*Phenomena of Planets and Satellites*, pages 454—487.—These are, for the most part, sufficiently explained in the body of the work. The following additional explanations are added for completeness:

*Disk of Mercury and Venus*, pages 454—455.—The angle  $\theta$ , needed in reducing meridian observations, is the angle which the arc of the great circle from the planet to the sun, makes with the arc from the planet toward the west, reckoned in the direction west, north, east, south. This position-angle is reckoned from  $0^\circ$  to  $360^\circ$ , as in the measurement of double stars, the planet taking the place of the central star. But its measure is  $90^\circ$  greater than that of a double star.

We may also regard  $\theta$  as expressing the angle which the line of cusps makes with the meridian, the positive direction of the meridian being toward the north, and the positive direction of the line of cusps that in which a person following this line would have the illuminated portion of the disk on his right.

*Satellites and Disk of Mars*, page 456.—This page gives the Washington mean time of the greatest eastern and western elongations, the position-angles, and the distance of the satellites from the centre of the planet during the month preceding and following opposition.

*Satellites of Jupiter*, pages 457—481.—The times of phenomena are explained at the foot of each page; the diagram is on page 457.

*Phenomena*, pages 488—489.—The conjunctions, quadratures, and oppositions of the planets with respect to the sun, give the hours when the longitude of each planet differs from that of the sun by  $0^\circ$ ,  $90^\circ$  or  $180^\circ$ .

The conjunctions of the moon and planets with each other are given in right ascension. The degrees and minutes to the right show the difference of declination at the moment of conjunction.

*Latitude by Observed Altitude of Polaris*.—Table IV replaces the Tables A, B, C, D, given as a *Supplement* to the volumes of the Ephemeris for 1874—1881, and is intended for use at sea and reconnaissance on land. It will furnish an approximate value of the latitude, the probable error of which, in so far as the table is concerned, will be a few tenths of a minute of arc.

The directions for using the table are adapted to a right ascension of Polaris equal to  $1^h 18^m 9$ . Somewhat greater accuracy may be insured by substituting the right ascension of Polaris at the date of observation, from pages 302—313 of this volume.

## APPENDIX.

### ON THE CONSTRUCTION OF THE AMERICAN EPHEMERIS AND NAUTICAL ALMANAC FOR 1894.

THE adopted constants of precession, nutation, and aberration are those of STRUVE and PETERS, namely:—

$$\begin{aligned} \text{Precession} &= 50'.2411 + 0''.0002268 t \\ \text{Nutation} &= 9'.2231 + 0''.000009 t \\ \text{Aberration} &= 20'.4451 \end{aligned}$$

in which  $t$  is the number of years after 1800.0.

The obliquity of the ecliptic is that of HANSEN's *Tables du Soleil*, which is 0'.31 greater than that of PETERS, given in the issues of this Ephemeris preceding that for 1882. A comparison of HANSEN's mean obliquity with that of PETERS and of LE VERRIER at different epochs is given in the following table:—

Epoch.	HANSEN.	PETERS.	LE VERRIER.	H.—P.	H.—L.
1750	23° 28' 18.19"	17.44"	19.42"	+ 0.75"	- 1.23"
1800	23° 27' 54.80"	54.22"	55.63"	+ 0.58"	- 0.83"
1850	23° 27' 31.42"	30.99"	31.83"	+ 0.43"	- 0.41"
1900	23° 27' 8.02"	7.76"	8.03"	+ 0.26"	- 0.01"

The formulæ for reducing the places of the fixed stars, page 280, correspond to the *Star Tables of the American Ephemeris*, Washington, 1869.

The mean right ascensions of stars have been reduced to NEWCOMB's fundamental standard in the catalogue attached to the *Washington Observations for 1870*, Appendix II, with the following exceptions: The right ascensions of the 48 circumpolar stars north of 60° north declination are from Dr. GOULD's *Standard Places of Fundamental Stars*, second edition, United States Coast Survey Office, 1866. Of the twelve stars south of 50° south declination, the positions of  $\beta$  Hydri,  $\alpha$  Trianguli Australis, and  $\sigma$  Octantis, have been corrected from data furnished by Dr. GOULD; while the remaining nine are, as before, from the *British Nautical Almanac* for 1848.

The right ascensions of the additional stars in the general list, whose apparent right ascensions are given in a subsequent section, have been taken partly from the *Catalogue of 1098 Standard Clock and Zodiacal Stars*, forming Part IV of Vol. I of *Astronomical Papers Prepared for the Use of the American Ephemeris and Nautical Almanac*, Washington, 1881; and partly from the catalogue of the Astronomische Gesellschaft of 1878. A few have been derived from recent catalogues without a rigorous reduction for equinox.

The mean declinations of stars are taken from BOSS's paper in the *Report of the Northern Boundary Commission*, Washington, 1879, for all stars found therein. The declinations of all the other stars have been reduced to the same standard, except those of the additional ones above, which have been taken partly from the Astronomische Gesellschaft list, and partly from places in recent catalogues. To the apparent places of Sirius and Procyon have been applied the periodic corrections resulting from AUWZER'S investigations.

The values of these corrections are:—

Year.	Sirius.	Procyon
1894.0	$\Delta \alpha = + 0.137$ $\Delta \delta = + 1.05''$	$\Delta \alpha = + 0.068$ $\Delta \delta = + 0.25''$
1895.0	$\Delta \alpha = + 0.116$ $\Delta \delta = + 1.27''$	$\Delta \alpha = + 0.070$ $\Delta \delta = + 0.08''$

The ephemeris of the sun is constructed from HANSEN and OLUFSEN's *Tables du Soleil*, Copenhagen, 1853, except that STRUVE's aberration has been used. This is equivalent to adding  $0'.19$  to the true longitudes, but it does not affect the right ascensions and declinations. The sun's rectangular equatorial co-ordinates have been computed from the longitudes and latitudes by the following formulæ:—

$$\begin{aligned} X &= R \cos \lambda \\ Y &= R \sin \lambda \cos \omega - 19.3 R \beta \\ Z &= R \sin \lambda \sin \omega + 44.5 R \beta \end{aligned}$$

The reductions to mean equinox, 1894.0, are computed by the formulæ,

$$\begin{aligned} \Delta X' &= + Y \sec \omega \Delta \lambda \sin 1'' \\ \Delta Y' &= - X \cos \omega \Delta \lambda \sin 1'' + Z \Delta \omega \sin 1'' - 9.4 \tau R \sin (\lambda + 187^\circ) \\ \Delta Z' &= - X \sin \omega \Delta \lambda \sin 1'' - Y \Delta \omega \sin 1'' + 21.7 \tau R \sin (\lambda + 187^\circ) \end{aligned}$$

Wherein—

- $\lambda$  and  $\beta$  are the longitude and latitude of the sun referred to the equinox and ecliptic of the date;
- $\omega$ , the obliquity of the ecliptic;
- $\Delta \lambda$ , the reduction of longitude for precession and nutation from January 0;
- $\Delta \omega$ , the reduction of the mean to the apparent obliquity;
- $\tau$ , the fraction of the year since January 0.

The numerical coefficients are in units of the seventh place of decimals. The correction for latitude has been taken from GOETZEL's paper in the *Astronomical Journal*, Vol. II, page 71.

The mean equatorial horizontal parallax of the sun, adopted from Professor NEWCOMB's *Investigation of the Distance of the Sun and the Elements which depend on it*,\* is  $8''.848$ . The adopted semidiameter of the sun at the earth's mean distance is  $16' 2''$ . In the computations pertaining to eclipses, BESSEL's semidiameter,  $15' 59''.788$  has been used.

The right ascension, declination and parallax of the moon are derived from HANSEN's *Tables de la Lune*, London, 1857, the mean longitude being corrected in accordance with NEWCOMB's *Researches on the Motion of the Moon*, Part I, page 268,† and a corrected table being substituted for Table XXXIV.

The semidiameter of the moon is computed from the moon's horizontal parallax by the formula,

$$S = 0.272274 \pi + 2''.5$$

The constant  $2''.5$  is omitted in the computation of eclipses and occultations, as due entirely to telescopic and ocular irradiation.

The ephemeris of Mercury is derived from Professor WINLOCK's *Tables of Mercury*, Washington, 1864. They are based on the older theory of LE VERRIER, published in the Additions to the *Connaissance des Temps* for 1848.

The ephemeris of Venus is derived from Mr. G. W. HILL's *Tables of Venus*, Washington, 1872.

The ephemeris of Mars is derived from manuscript tables constructed from LINDENAU's Tables. Mr. HUGH BREEN's results, contained in his paper *On the Corrections of LINDENAU's Elements of Mars*, published in the *Memoirs of the Royal Astronomical Society*, Vol. XX, have also been discussed and applied; and LE VERRIER's secular variations of the elements are likewise adopted. The perturbations produced by Jupiter have been increased by  $\frac{1}{10}$  of their value. The following are the corresponding corrected elements and annual variations for Washington, 1855.0:—

$$\begin{aligned} L &= 320^\circ 13' 33''.87 + 689101''.1527 \tau \\ \pi &= 333^\circ 23' 17.84 + 65.9990 \tau \\ \Omega &= 48^\circ 25' 55.29 + 27.6997 \tau \\ i &= 1^\circ 51' 2.20 - 0.02141 \tau \\ e &= 19238''.75 + 0.18549 \tau \\ n &= 689050''.8927 \\ a &= 1.5236915 \end{aligned}$$

The ephemeris of Jupiter is derived from manuscript tables constructed from BOUVARD's Tables, with such changes as were required to make them correspond more nearly to the formulæ.

The ephemeris of Saturn is derived from a provisional theory constructed by Mr. GEORGE W. HILL, and still unpublished.

The ephemerides of Uranus and Neptune are derived from Professor NEWCOMB's Tables, published by the *Smithsonian Institution*.

\* *Astronomical Observations made at the U. S. Naval Observatory, Washington, 1865*, Appendix II.

† *Astronomical Observations made at the U. S. Naval Observatory, Washington, 1875*, Appendix II.

The semidiameters of the planets are computed from the following values:—

	Semidiameter.	Log Dist.	Authority.
Mercury	3.34 "	0.00	LE VERRIER, <i>Theory of Mercury</i> .
Venus	8.546 $\pm$ 0.086	0.00	
Mars	2.842 $\pm$ 0.057	0.25	
Jupiter (polar)	18.78 $\pm$ 0.067	0.70	
Saturn (polar)	8.77 $\pm$ 0.039	0.95	
Uranus	1.68 $\pm$ 0.3	1.30	
Neptune	1.28	1.48	
Jupiter (equatorial)	20.00	0.70	
Saturn (equatorial)	9.38	0.95	

The elements of eclipses of the sun and occultations of stars by the moon are adapted to BESSEL's method, using the special forms in CHAUVENET's *Spherical and Practical Astronomy*. The adopted semidiameters are:—

$$\begin{aligned} \text{Semidiameter of the sun at distance unity.} & . . . . . 959\overset{\prime}{.}788 \\ \text{Ratio of radius of moon to radius of earth} & . . . . . 0.27227 \end{aligned}$$

The eclipses of Jupiter's satellites are computed from TODD'S *Continuation of DAMOISEAU'S Tables*, Washington, 1876. The occultations, transits, etc., are computed from WOOLHOUSE'S Tables, *British Nautical Almanac* for 1835, Table II of each satellite having been adapted to DAMOISEAU'S Tables.

The elongations and conjunctions of the satellites of Saturn, except those of Titan and Hyperion, are computed from HALL'S Tables, published in Washington observations of 1882–1883.

The apparent elements of the rings of Saturn are computed from BESSEL'S data, except those for the dusky ring.

The elongations of the satellites of Uranus, and of the satellite of Neptune are computed from the data of Professor NEWCOMB'S *Uranian and Neptunian Systems*, Washington, 1875.

In compiling the positions of observatories, the latest available data have been used. The positions have been furnished, in many instances, through the courtesy of the directors of the Observatories, in response to a circular issued by the Superintendent of the American Ephemeris.

The reduction to geocentric latitude, and the logarithm of the radius of the earth, are derived from BESSEL'S elements of the terrestrial spheroid, as adopted in Table III of CHAUVENET'S *Spherical and Practical Astronomy*, Vol. II:—

$$\log e = 8.9122052$$

$$\varphi' - \varphi = -11' 30''.65 \sin 2\varphi + 1''.16 \sin 4\varphi$$

$$\log \rho = 9.9992747 + 0.0007271 \cos 2\varphi - 0.0000018 \cos 4\varphi$$

Table IV, for finding the latitude from an observed altitude of Polaris, is constructed for—

(1) An altitude of Polaris equal to 45°.

(2) A declination of Polaris equal to + 88° 44'.

The principal computations of the Ephemeris have been distributed in the following manner:—

The ephemeris of the Sun was computed by Mr. E. DAVIS; the Moon's longitude, latitude, semidiameter and horizontal parallax, by Professor KEITH; the right ascension and declination, by Professor VAN VLECK; the culminations, by Dr. J. MORRISON; the lunar distances, by Mr. BRADFORD; Mercury and Venus, by Mr. E. P. AUSTIN; Mars, Jupiter, Saturn, Uranus, and Neptune, by Mr. ROBERDEAU BUCHANAN; Jupiter's satellites, by Professor H. D. TODD; the satellites of Mars, Saturn, Uranus, and Neptune, by Dr. MORRISON. The mean and apparent places of the fixed stars were prepared by Mr. MEIER and Mr. HEDRICK; the general constants for their reduction, by Mr. BUCHANAN; the occultations, by Mr. AUHAGEN; and the eclipses were computed and the charts projected by Mr. BUCHANAN.

The correction is to be added to the approximate Greenwich time when the proportional logarithms in the Ephemeris are decreasing, and subtracted when they are increasing.

TABLE IV.—LATITUDE BY POLARIS.

**TABLE FOR FINDING THE LATITUDE BY AN OBSERVED ALTITUDE OF POLARIS.**

Reduce the observed altitude of Polaris to the true altitude.

Reduce the recorded time of observation to local sidereal time.

If the sidereal time is  $\begin{cases} \text{less than } 1^h 20^m.1, \text{ subtract it from } 1^h 20^m.1; \\ \text{between } 1^h 20^m.1 \text{ and } 13^h 20^m.1, \text{ subtract } 1^h 20^m.1 \text{ from it;} \\ \text{greater than } 13^h 20^m.1, \text{ subtract it from } 25^h 20^m.1; \end{cases}$

and the remainder is the hour-angle of Polaris.

With this hour-angle take out the correction from Table IV (below), and add it to or subtract it from the true altitude, according to its sign. The result is the latitude of the place.

*Example.*—1894, November 10, at 9<sup>h</sup> 29<sup>m</sup> 29<sup>s</sup>, P. M., mean solar time, in longitude 29° east of Greenwich, suppose the true altitude of Polaris to be 29° 29': required the latitude of the place.

	h m s
Local astronomical mean time . . . . .	9 29 29
Reduction from Table III, for 9 <sup>h</sup> 29 <sup>m</sup> 29 <sup>s</sup> . . . . .	+ 1 34
Greenwich sidereal time of mean noon, November 10, page 183 . . . . .	15 19 28.3
Reduction from Table III, for longitude (= 1 <sup>h</sup> 56 <sup>m</sup> east, or minus) . . . . .	— 0 19
Sum (having regard to signs) is equal to local sidereal time . . . . .	0 50 12.3
	h m s
Subtract sidereal time . . . . .	1 20 6
Remainder is equal to hour-angle of Polaris . . . . .	0 50 12.3
True altitude . . . . .	+ 29 29.0
Correction from Table IV (below) . . . . .	— 1 14.8
Approximate Latitude . . . . .	+ 28 14.2
